Structured Abstract

Purpose: We conducted a systematic evidence review of the benefits and harms of behavioral counseling interventions to prevent cardiovascular disease (CVD) in persons with established risk factors to assist the U.S. Preventive Services Task Force (USPSTF) in updating its previous recommendation statements.

Data Sources: We searched MEDLINE, PsycInfo, the Database of Abstracts of Reviews of Effects, and the Cochrane Central Register of Controlled Trials from 2001 through October 2013 to locate relevant trials for all key questions published since the previous reviews in support of prior recommendations. We supplemented our searches with reference lists from relevant existing systematic reviews, suggestions from experts, and information from Clinicaltrials.gov to identify ongoing trials.

Study Selection: Two investigators independently reviewed 7,218 abstracts and 553 articles against a set of a priori inclusion criteria. Investigators also independently critically appraised each study using design-specific quality criteria based on USPSTF methods. We included fair- or good-quality trials evaluating behavioral counseling interventions to promote a healthy diet, physical activity, or both in persons with CVD risk factors, including hypertension, dyslipidemia, metabolic syndrome, and impaired fasting glucose or glucose tolerance. We resolved discrepancies by consensus.

Data Extraction and Analysis: One investigator abstracted data from 74 included studies into evidence tables and a second reviewer checked these data. We conducted meta-analyses on 57 of the 71 trials that provided necessary data to estimate the effect size of counseling on intermediate health outcomes (lipids, blood pressure, weight measures, and glucose measures). We qualitatively summarized the evidence for effects on health outcomes, behavioral outcomes, and harms.

Data Synthesis: *Key Question 1. Do healthy lifestyle counseling interventions improve CVD health outcomes in adults with known CVD risk factors?* Only a subset of trials (k=16) reported measures of patient health outcomes, including CVD events (k=5) and self-reported measures of quality of life (QOL) or depression symptoms (k=11). In general, intensive interventions that combined lifestyle interventions did not reduce CVD events or mortality at up to 10 years of followup, although event rates were generally low. In one early good-quality trial, a high-intensity behavioral counseling intervention in conjunction with a protocol to start medication reduced CVD events at 6.6 years compared with usual care (relative risk [RR], 0.71 [95% CI, 0.51 to 0.99]). This study was conducted in Swedish men at high risk for CVD (which included persons with diabetes and known CVD). Overall, combined lifestyle interventions did not appear to improve self-reported depression symptoms (k=4) in persons with impaired fasting glucose or glucose tolerance at 6 to 12 months. Findings that showed a benefit on self-reported QOL measures were mixed. While three combined lifestyle counseling trials showed improvement on selected QOL measures, two combined lifestyle counseling trials and two physical activity-only counseling trials showed no benefit on self-reported QOL at 6 to 12 months.

Key Question 2. Do healthy lifestyle counseling interventions improve intermediate CVD outcomes in adults with known CVD risk factors? Medium- (31 to 360 minutes) to high-intensity (>360 minutes) combined lifestyle counseling in persons selected for CVD risk factors reduces total cholesterol, low-density lipoprotein (LDL) cholesterol, blood pressure, fasting glucose, diabetes incidence, and weight outcomes. Overall, at 12 to 24 months, behavioral counseling appears to reduce total cholesterol (k=34) by an average of 4.48 mg/dL (95% CI, 6.36 to 2.59), LDL cholesterol (k=25) by 3.43 mg/dL (95% CI, 5.37 to 1.49), systolic blood pressure (k=31) by 2.03 mm Hg (95% CI, 2.91 to 1.15), diastolic blood pressure (k=24) by 1.38 mm Hg (95% CI, 1.92 to 0.84), fasting glucose (k=22) by 2.08 mg/dL (95% CI, 3.29 to 0.88), diabetes incidence (k=8) by an RR of 0.58 (95% CI, 0.37 to 0.89), and weight outcomes (k=34) by a pooled mean difference of 0.26, using standardized units (95% CI, 0.35 to 0.16). There was substantial statistical heterogeneity for weight outcomes. High-intensity combined lifestyle counseling in persons with impaired fasting glucose or glucose tolerance (k=5) can reduce diabetes incidence in the long term (RR, 0.55 [95% CI, 0.45 to 0.67]). Intensive diet-only counseling interventions primarily in persons with dyslipidemia who are not yet taking medications can also modestly lower total (k=8) and LDL (k=7) cholesterol at 12 to 24 months. In contrast, medium-intensity (k=8) physical activity–only counseling interventions (k=10) did not appear to improve intermediate CVD outcomes at 12 to 24 months. Findings from trials that could not be included in quantitative analyses were generally consistent with pooled findings.

Key Question 3. Do healthy lifestyle counseling interventions improve diet and physical activity behavioral outcomes in adults with known CVD risk factors? Overall, objectively measured and self-reported changes in dietary intake and physical activity were concordant with intermediate outcome findings. Only three of the 61 trials that reported behavioral outcomes did not also report intermediate health outcomes. In selected trials conducted in persons who were already taking medications to lower cholesterol or blood pressure, counseling interventions appeared to improve dietary intake and physical activity despite a lack of benefit on lipid or blood pressure outcomes. Many physical activity–only counseling trials (k=9) had less than 12 months of followup. Four of five trials reporting behavioral outcomes at 12 to 24 months found statistically significant improvements in self-reported physical activity (i.e., number of persons meeting the recommended 150 minutes of moderate activity per week, minutes per week of total or moderate physical activity).

Key Question 4. What are the adverse effects of healthy lifestyle counseling in adults with known CVD risk factors? We examined all included counseling trials for harms, including any paradoxical change in outcomes. While we searched for additional studies examining harms of healthy lifestyle counseling interventions, we did not find any. Overall, harms (or lack thereof) were not commonly reported (k=10). In general, included interventions did not have significant adverse effects, except for two persons who had serious events resulting from physical activity in one trial targeting older adults. Reported increases in carbohydrate intake (k=8) were accompanied by dietary improvements in fat, saturated fat, fiber, or fruits and vegetables, without an overall increase in sugar or total calories consumed.

Limitations: Only a small subset of trials reported patient health outcomes, longer-term followup of intermediate and behavioral outcomes, and harms. We were unable to identify important contributors to statistical heterogeneity other than gross categorizations of type of

population or intervention.

Conclusions: Medium- and high-intensity diet and physical activity behavioral counseling in overweight or obese persons with CVD risk factors resulted in consistent improvements across a variety of important cardiovascular intermediate health outcomes up to 2 years. High-intensity combined lifestyle counseling reduced diabetes incidence in the longer term. The applicability of these findings depends largely on the availability of intensive counseling in practice and real-world fidelity and adherence to these interventions.

Chapter 1. Introduction

Purpose

The U.S. Preventive Services Task Force (USPSTF) will use this report to update its 2002 and 2003 recommendations on primary care–relevant behavioral counseling to promote a healthy diet and physical activity in adults with traditional risk factors for cardiovascular disease (CVD).

Definitions

Healthy Diet

A healthy diet promotes health and reduces an individual’s risk for chronic disease through nutritious eating patterns. For the purposes of this review, we will include any dietary counseling interventions that promote a balanced diet (e.g., appropriate energy content); balance of fats (e.g., consumption of mono and poly unsaturated fats, omega-3 fats, avoidance of excess saturated fat, avoidance of trans fat); increased consumption of fruits and vegetables; increased consumption of legumes; increased consumption of lean proteins; increased consumption of nonfat or low-fat dairy; balance of carbohydrates (e.g., consumption of whole grain and fiber; avoidance of excess refined carbohydrates, including excess sweetened beverages); and avoidance of excess sodium. This guidance is generally consistent with dietary recommendations of a number of groups, including the Institute of Medicine, the World Health Organization, the U.S. Department of Health and Human Services (DHHS), the U.S. Department of Agriculture, the Academy of Nutrition and Dietetics (previously the American Dietetic Association), the Centers for Disease Control and Prevention (CDC), the American Heart Association (AHA) and American College of Cardiology (ACC), the American Cancer Society, and the American Diabetes Association. We did not review dietary counseling interventions that only focused on micronutrient intake, vitamin and/or antioxidant supplementation, or alcohol moderation.

Physical Activity

Although no internationally accepted definition of physical activity exists, American researchers have defined physical activity as “bodily movement produced by the contraction of skeletal muscle that increases energy expenditure above the basal level.”¹ DHHS and other organizations²⁻⁴ recommend that adults age 18 years and older should engage in at least 150 minutes of moderate-intensity or 75 minutes of vigorous-intensity aerobic physical activity per week, in addition to engaging in strengthening activities at least twice per week. Based on these definitions, this review focused on counseling interventions promoting aerobic- or strength-related physical activity. We did not review counseling that focused primarily on flexibility or balance.

Cardiovascular Risk Factors

Risk factors for CVD are well established and include both modifiable and nonmodifiable components. Modifiable risk factors include: dyslipidemia or hyperlipidemia (referred to as dyslipidemia in this report), hypertension, diabetes, overweight and obesity, smoking, lack of physical activity, and unhealthy diet.⁵⁻⁷ Nonmodifiable risk factors include: age, sex, and family history.^{5,6}

This review focuses on patients who are at high risk for CVD, which we defined as having one or more of the following risk factors: dyslipidemia, hypertension, impaired fasting glucose/impaired glucose tolerance, and/or metabolic syndrome. Metabolic syndrome is a clustering of metabolic risk factors that include abdominal obesity, dyslipidemia, increased blood pressure, insulin resistance, or glucose intolerance. While diabetes is a strong risk factor for CVD,^{8,9} we considered existing diabetes to be a CVD risk equivalent. As such, we did not review studies primarily aimed at patients with diabetes or pre-existing coronary heart disease, cerebrovascular disease, peripheral artery disease, or severe chronic kidney disease.

Prevalence and Burden of Preventable Illness

Diseases associated with modifiable risk factors are the leading causes of illness and death in the United States.¹⁰ CVD is the leading cause of death in the United States and nearly a quarter of CVD deaths are considered avoidable.^{11,12} Declines in cardiovascular mortality in recent decades have been attributed to improvements in modifiable risk factors, including reductions in blood pressure, cholesterol, and physical inactivity.¹³

A substantial portion of the U.S. population has at least one modifiable risk factor for CVD. In 2009–2010, for example, the overall age-adjusted prevalence of hypertension among U.S. adults was approximately 29 percent.¹⁴ During this same time period, an estimated 13 percent of adults had high total cholesterol and 21 percent had low high-density lipoprotein (HDL) cholesterol.¹⁵ In 2007–2010, the overall prevalence of high low-density lipoprotein (LDL) cholesterol was 27 percent in the United States.¹⁶ National Health and Nutrition Examination Survey (NHANES) data from 2005–2006 indicate that about 30 percent of U.S. adults have impaired fasting glucose or impaired glucose tolerance.¹⁷ Likewise, 2003–2006 NHANES data show a 34 percent prevalence of metabolic syndrome.¹⁸ In 2011, 19 percent of U.S. adults smoked cigarettes.¹⁹ While the prevalence of hypertension and dyslipidemia has declined in the United States, these conditions are still very common, and adequate control of these risk factors remains suboptimal.^{14,20,21}

Cardiovascular risk factors and CVD burden is not equally distributed across the U.S. population. Certain groups experience a higher prevalence of risk factors and rates of avoidable death from CVD, including older adults, men, persons with low income, and some racial/ethnic groups.^{12,14,15, 17,22} Selected examples of the large variation in the distribution of risk factors include: the prevalence of hypertension is approximately 67 percent in adults age 60 years and older and just 7 percent in younger adults ages 18 to 39 years,¹⁴ and the prevalence of hypertension is 40 percent in blacks compared with 26 percent in Hispanics and 27 percent in

nonHispanic whites.¹⁴ Similarly, poor Americans are nearly twice as likely to smoke as the nonpoor (28% vs. 16%).¹⁹ Finally, the avoidable death rate for CVD among blacks is almost twice that of whites.¹²

Dietary and Physical Activity Behaviors in the United States

Observational research consistently shows that a healthy diet and physical activity are associated with benefits in important health outcomes, including reductions in cardiovascular events and all-cause mortality.²³⁻³¹ Despite this convincing evidence, however, U.S. adults do not comply with healthy diet and physical activity recommendations.^{32,33} According to NHANES data from 2005–2006, greater than 30 percent of men and 32 percent of women do not engage in any leisure time physical activity. Previous years of NHANES data reveal that rates of physical activity did not significantly improve from 1999 to 2006 for men or women.³⁴ Similarly, greater than 81 percent of men and 70 percent of women eat a poor diet, which is defined by inadequate consumption of fruits/vegetables, fish, and whole grains and excess intake of sodium and sweets/sugar-sweetened beverages.³⁴ Adherence to an ideal diet has improved only minimally from 1999 to 2008 (0.3% to 0.6% for men and 0.9% to 1.4% for women).³⁴ Some research shows that high-risk adults are even less likely to adhere to healthy lifestyle behaviors than their lower-risk counterparts. An analysis of NHANES data from 2001 to 2006 found that adults with hypertension or dyslipidemia were less likely to adhere to five healthy lifestyle habits (including consuming five or more fruits/vegetables per day, regular exercise, maintaining a healthy weight, moderate alcohol consumption, and not smoking) than adults with no CVD or its risk factors (5% and 8%, respectively, vs. 11%).³⁵ Secondary analysis of 1999–2004 NHANES data for adults with hypertension found that 20 percent of individuals adhered to DASH (Dietary Approaches to Stop Hypertension) dietary recommendations, which emphasize fruits, vegetables, whole grains, and low-fat dairy consumption while limiting sugar-sweetened foods and beverages, reducing red meat consumption, and avoiding added fats.³⁶

There is also a marked disparity in healthy diet and physical activity behaviors by important subpopulations. Persons of lower socioeconomic status or those with lower educational attainment tend to exercise less, eat fewer fruits and vegetables, and eat fewer foods rich in dietary fiber compared with those in a higher socioeconomic position or with higher educational attainment.³⁷⁻³⁹ Nonwhites tend to exercise less than whites,^{39,40} and blacks consume fewer servings of fruits and vegetables than whites.^{37,41,42} Physical activity rates are lower in older persons and women than in younger persons and men.^{39,43} Major barriers to healthy eating include: low income, food marketing, lack of accessible and accurate information on what constitutes a healthy diet, poor accessibility to affordable healthy foods, lack of opportunity to experiment and to develop cooking skills (e.g., poor literacy, reduced access to well-equipped kitchens, homelessness, poor educational attainment), and sociocultural factors (e.g., family or cultural food norms, family resistance, lack of support, and child care demands can all inhibit dietary change). Major barriers to physical activity in adults include: high costs of exercise facilities, exercise equipment, and sports teams; poor access to facilities; and unsafe or unsupportive environments.^{39,44} Psychosocial barriers to physical activity include: anxiety about unfamiliar settings for exercise, poor body image, lack of social support for exercise, low self-efficacy for maintaining an exercise program, and lack of belief in the benefits of exercise.³⁹

Current Clinical Practice in the United States

Consistent with the 2002 USPSTF recommendation, the American Academy of Family Physicians recommends that primary care physicians or other qualified professionals provide intensive behavioral dietary counseling for adults with dyslipidemia and other known risk factors for cardiovascular and diet-related chronic disease.⁴⁵ The American College of Physicians has endorsed the USPSTF recommendation and other organizations, including the AHA and Academy of Nutrition and Dietetics, have produced similar guidance.⁴⁶⁻⁴⁹

Although patients perceive family doctors as one of the most reliable sources of information on food and nutrition,⁵⁰ dietary counseling practices of primary care clinicians fall short of recommendations, even for patients at high risk for CVD. A 2002 survey showed that among adults with hypertension, just 21 percent reported being advised by a physician or other health professional to start a diet or change their eating habits and 22 percent reported receiving advice to reduce their sodium intake.⁵¹ A direct observation study of family medicine visits found that although diet was discussed in 31 percent of visits, offers of assistance and followup were infrequent (17% and 10% of visits, respectively).⁵²

Despite improvements in physician advice to encourage physical activity over the past decade, the prevalence of physical activity counseling remains low. The 2010 National Health Interview Survey, for example, showed that approximately 44 percent of adults with hypertension reported that their physician recommended they exercise (up from 34% in 2000).⁵³ This survey found a higher proportion of physical activity advice among adults with chronic conditions, including CVD and diabetes, compared with the overall population (32%). A recent systematic review of providers' attitudes toward physical activity counseling found that most primary care providers agree that such counseling is important and that they have a role in promoting physical activity to their patients.⁵⁴ Barriers to physical activity counseling cited by providers, however, are substantial and include: lack of time, lack of knowledge or training about physical activity counseling, and lack of success with changing patient behavior.⁵⁴

Previous USPSTF Recommendations

In 2012, the USPSTF updated the recommendation for adults without pre-existing CVD or its risk factors, concluding that the average benefit of behavioral counseling interventions in primary care to promote a healthy diet and/or physical activity for CVD prevention is small, and that clinicians may consider selectively providing or referring individual patients for medium- or high-intensity behavioral counseling interventions (C recommendation).

The 2012 recommendation did not address counseling in persons with known traditional CVD risk factors. In 2002, the USPSTF issued separate recommendations for healthy diet and physical activity counseling, both of which included persons with cardiovascular risk factors (as well as unselected persons). In 2002, the USPSTF recommended intensive behavioral dietary counseling for adult patients with hyperlipidemia and other known risk factors for cardiovascular and diet-related chronic disease (B recommendation). It concluded, however, that the evidence was insufficient to recommend for or against behavioral counseling in primary care settings to

promote physical activity (I statement).

In 2012, the USPSTF issued a related recommendation on screening for and management of adult obesity. It recommended screening all adults for obesity, and that clinicians should offer or refer obese patients to intensive, multicomponent behavioral interventions (B recommendation).

As a result, we conducted this systematic review to support the USPSTF in updating its 2002 recommendations on primary care–relevant behavioral counseling to promote a healthy diet and physical activity in patients with known CVD risk factors. This review was designed to complement the existing systematic reviews that supported the 2012 USPSTF recommendations and, therefore, does not include healthy lifestyle interventions aimed at persons without CVD risk factors or interventions primarily aimed at weight loss or weight management.

Chapter 2. Methods

Scope and Purpose

This systematic review was designed to complement the systematic review supporting the 2012 USPSTF recommendation that focused on healthy lifestyle counseling for individuals without pre-existing CVD or its risk factors.⁵⁵ For this review, we adapted our previous analytic framework and key questions to address the benefits and harms of primary care–relevant counseling interventions to improve diet and physical activity in adults with known cardiovascular risk factors (e.g., hypertension, dyslipidemia, impaired fasting glucose or glucose tolerance, metabolic syndrome), but without pre-existing CVD.

Analytic Framework and Key Questions

Using the USPSTF’s methods (detailed in **Appendix A**),⁵⁶ we developed an analytic framework (**Figure 1**) and four key questions (KQs):

1. Do primary care–relevant behavioral counseling interventions for healthy diet and/or physical activity improve CVD health outcomes (e.g., prevent morbidity and mortality) in adults with known CVD risk factors (e.g., hypertension, dyslipidemia, impaired fasting glucose, metabolic syndrome)?
 - a. Are there population or intervention characteristics that influence the effectiveness of the interventions?
2. Do primary care–relevant behavioral counseling interventions for physical activity and/or healthy diet improve intermediate outcomes associated with CVD (e.g., blood pressure, lipids, glucose, weight) in adults with known CVD risk factors (e.g., hypertension, dyslipidemia, impaired fasting glucose, metabolic syndrome)?
 - a. Are there population or intervention characteristics that influence the effectiveness of the interventions?
3. Do primary care–relevant behavioral counseling interventions for physical activity and/or healthy diet change associated health behaviors in adults with known CVD risk factors (e.g., hypertension, dyslipidemia, impaired fasting glucose, metabolic syndrome)?
 - a. Are there population or intervention characteristics that influence the effectiveness of the interventions?
4. What are the adverse effects of primary care–relevant behavioral counseling interventions for physical activity and/or healthy diet in adults with known CVD risk factors (e.g., hypertension, dyslipidemia, impaired fasting glucose, metabolic syndrome)?

Data Sources and Searches

We designed this review to serve as an extension of our prior systematic review that was completed in 2009.⁵⁵ As such, we examined all included and excluded studies from that systematic review, paying particular attention to excluded studies in persons with CVD risk

factors. The literature search for this systematic review includes searches from MEDLINE, PubMed, PsycInfo, the Database of Abstracts of Reviews of Effects, and the Cochrane Central Register of Controlled Trials from January 2001 through October 2013. We also searched for recent relevant existing systematic reviews on healthy lifestyle counseling in persons with CVD risk factors from January 2008 through January 2013 in MEDLINE, the Cochrane Database of Systematic Reviews, and the Database of Abstracts of Reviews of Effects, and publications from the Institute of Medicine, the Agency for Healthcare Research and Quality (AHRQ), and the National Institute of Health and Clinical Excellence. We worked with a medical librarian to develop our search strategy (**Appendix A Table 1**) and all searches were limited to articles published in the English language. We managed the literature search results using version 12.0 of Reference Manager® (Thomson Reuters, New York, NY), a bibliographic management software database.

To ensure the comprehensiveness of our search strategy, we reviewed the reference lists of included studies and relevant systematic reviews and meta-analyses to identify relevant articles that were published before the timeframe of or not identified in our literature searches. We also supplemented our database searches with suggestions from experts and searched Clinicaltrials.gov to identify relevant ongoing trials (**Appendix B**).

Study Selection

Two investigators independently reviewed the titles and abstracts of 7,218 identified articles to determine if the study met the inclusion and exclusion criteria for design, population, intervention, and outcomes (**Appendix A Figure 1**). Two reviewers then independently evaluated 553 full-text articles of potentially included studies against the complete inclusion and exclusion criteria (**Appendix A Table 1**). We resolved disagreements by discussion and consultation with a third reviewer, if necessary. Excluded studies and reasons for their exclusion are listed in **Appendix C**.

We developed an a priori set of inclusion and exclusion criteria (**Appendix A Table 1**). We included studies in adults who had at least one cardiovascular risk factor, including hypertension, dyslipidemia, impaired fasting glucose or glucose tolerance, and metabolic syndrome. We excluded trials in persons with known CVD (i.e., coronary artery disease [CAD], cerebrovascular disease, peripheral artery disease), severe chronic kidney disease, and diabetes. While diabetes is a strong risk factor for CVD,^{8,9} we considered existing diabetes to be a CVD risk equivalent. As such, we excluded trials evaluating lifestyle counseling interventions for the management of diabetes. While many included trials targeted persons with a combination of risk factors, including smoking and obesity, we did not find any diet and/or exercise counseling trials that selected persons exclusively based on smoking history. We excluded populations in which obesity was the only CVD risk factor, as these trials recruited persons exclusively for obesity with a primary aim of weight loss or weight management. These trials were excluded because this evidence base is covered by a separate systematic review conducted for the USPSTF;⁵⁷ the USPSTF issued a separate recommendation statement in 2012 for the management of obesity in adults.⁵⁸ We also excluded populations with increased risk for CVD (e.g., due to physical inactivity, prehypertension), but without traditional CVD risk factors. Again, these trials were

covered by a separate systematic review⁵⁵ and are addressed in the 2012 USPSTF recommendation on healthy lifestyle behavioral counseling.⁵⁹

We included behaviorally-based counseling interventions to promote a healthy diet, physical activity, or both. Counseling interventions could be delivered alone or as part of a multicomponent intervention. Interventions had to be either conducted in primary care or judged to be feasible for delivery or referral from primary care. Therefore, we excluded interventions delivered through nonreferable community settings (e.g., work sites, churches). We included physical activity interventions that incorporated activities such as walking, cycling, swimming, or resistance training. We included healthy diet interventions aiming to change dietary behavior or improve or maintain cardiovascular health through a balanced diet (e.g., appropriate calorie intake; increased fruits and vegetables, whole grains, and fiber; balanced fats intake; and decreased sodium). We excluded interventions that were primarily aimed at evaluating if behavior change (i.e., improved diet or increased physical activity) resulted in physiologic or health benefits, as opposed to including interventions aimed at evaluating if counseling could change behavior. Therefore, we generally excluded interventions that focused on providing controlled diets or supervised physical activity. However, we included counseling interventions if they provided limited samples of foods or access to (optional) guided physical activity. We excluded counseling interventions primarily aimed at weight loss, falls or fracture prevention, or cognitive functioning, rather than CVD prevention.

Given the maturity and volume of literature, we focused on the most rigorous and most applicable evidence. Therefore, we limited studies of efficacy or effectiveness to fair- to good-quality randomized, controlled trials or controlled clinical trials that were conducted in developed countries and whose results were published in 1990 or later. Included trials had to compare an active intervention with usual care, a minimal intervention, or an attention control group. Because usual care for persons with known cardiovascular risk factors includes lifestyle counseling, we allowed included trials to use comparator groups that received nontailored printed materials, a single annual session (limited to 45 to 60 minutes), or two to three brief sessions annually (limited to 15 minutes each). We required that included trials have a followup duration of 6 months or greater. We examined health outcomes, including morbidity or mortality related to CVD. Intermediate health outcomes, or physiologic outcomes, included blood pressure, total cholesterol, LDL cholesterol, HDL cholesterol, fasting serum glucose, glucose tolerance, hemoglobin A1c, weight, and body mass index (BMI). Consistent with current USPSTF methods, true health outcomes (KQ 1) are those that are experienced by the patient. Therefore, we considered disease incidence (e.g., diabetes) and changes in CVD risk score as intermediate outcomes (KQ 2), as opposed to health outcomes (KQ 1), for this review. We accepted a number of behavioral outcomes, including self-reported dietary intake, self-reported physical activity, or objectively measured markers of behavior change, such as VO₂max and urinary sodium. We also included observational studies that reported serious harms (i.e., adverse events resulting in unexpected or unwanted medical attention), but did not include case series or case reports.

Data Extraction and Quality Assessment

One reviewer extracted data from all included studies rated as fair or good quality into a standard evidence table. A second reviewer checked the data for accuracy. The reviewers abstracted population characteristics (e.g., details about baseline demographics and baseline CVD risk), study design elements (e.g., recruitment procedures, inclusion/exclusion criteria, duration of followup and attrition), intervention and control characteristics (e.g., content, format, setting, number and length of sessions, duration, provider), any behavioral outcomes related to healthy diet and physical activity, and intermediate health outcomes (e.g., blood pressure, lipids, glucose tolerance, measures of weight, medication use, diabetes incidence, composite CVD risk), as well as patient health outcomes (e.g., mortality, CVD events, quality of life [QOL]) and harms (**Appendix D Tables 1–9; Appendix E Table 1**).

Two reviewers independently appraised all articles that met inclusion criteria using the USPSTF’s design-specific quality criteria,⁶⁰ which we supplemented with the National Institute for Health and Clinical Excellence methodology checklists (**Appendix A Table 2**).⁶¹ We rated articles as good, fair, or poor quality. In general, a good-quality study met all criteria well. A fair-quality study did not meet, or it was unclear if it met, at least one criterion, but also had no known important limitation that could invalidate its results. A poor-quality study had important limitations, or a fatal flaw, that would invalidate results. We excluded poor-quality studies from this review. Poor-quality studies had important limitations, including one or more of the following risks for bias: very high attrition (>40%), with or without differential attrition between intervention arms; lack of randomization, with biased assignment of participants to intervention arms, often with differences in or no reporting of baseline characteristics, per protocol analyses only; and poor description of methods that did not allow for adequate quality assessment.

Data Synthesis and Analysis

Because of the clinical heterogeneity across this body of evidence, we separately analyzed identified evidence according to how populations were targeted or defined (i.e., dyslipidemia, hypertension, impaired fasting glucose or glucose tolerance, or mixed risk factors), as well as according to type of intervention evaluated (i.e., focus on dietary counseling alone, physical activity alone, or both diet and physical activity counseling). We used summary tables to describe key characteristics of trials capturing the major sources of heterogeneity among included trials and results for the multiple outcomes reported for each trial.

We conducted random-effects meta-analyses using the DerSimonian and Laird method to estimate the effect size of counseling on intermediate health outcomes (KQ 2) (i.e., weight or BMI; systolic and diastolic blood pressure; total, HDL, or LDL cholesterol; triglycerides; fasting blood glucose; and diabetes incidence).⁶² Other measures of adiposity (i.e., waist circumference) and glucose (i.e., hemoglobin A1c, 1- or 2-hour glucose tolerance) were not as commonly reported. We conducted qualitative synthesis of health outcomes (KQ 1) and harms (KQ 4) given the sparse reporting of these outcomes. We also conducted qualitative syntheses of behavioral outcomes (KQ 3) (e.g., self-reported physical activity; objectively measured fitness; intake of total energy, fat, saturated fat, fiber, fruits and vegetables; and urinary sodium as a measure of

sodium intake) because of the wide variation in reporting of these outcome measures across included trials. Outcome analyses were also stratified by length of followup after randomization. Short-term followup included outcome measurements from 6 to less than 12 months. Intermediate-term followup included outcome measurements from 12 to 24 months. Long-term followup included outcome measurements after 24 months. Because the interventions were quite variable in their duration, the length of followup does not reflect duration of effect postintervention. We also used intervention intensity as a key characteristic of heterogeneity. Low-intensity interventions were estimated to include 30 minutes or less of contact with providers. These trials generally included only a single contact, two very brief contacts, or mail-only interventions. Medium-intensity interventions were estimated to involve greater than 30 minutes, but less than 6 hours, of contact with providers (e.g., 1-hour group meeting monthly for up to 6 months). High-intensity interventions were estimated to involve greater than 6 hours of contact. Because many articles did not report detailed information about the duration of contact, these categorizations often involved some reviewer judgment. As such, at least one other team member reviewed the studies' categorizations, and we resolved discrepancies through discussion.

For all intermediate health outcomes, we pooled the difference in change from baseline to followup between groups. We converted all outcomes to a common metric (e.g., mg/dL, mm Hg, lb) using standard conversion factors.⁶³ We calculated the pooled weighted mean difference separately for short-, intermediate-, and long-term followup. For weight outcomes, we estimated a standardized mean difference because measures could be either weight (lb) or BMI (kg/m²). If there were multiple intervention arms, we selected the most intensive or comprehensive arm to include in the meta-analysis. If the active intervention arms were of similar intensity and comprehensiveness, we calculated combined means and standard deviations using standard formulas. We adjusted results for cluster-randomized trials, but did not report adjusting for the clustering effect.

We assessed the presence of statistical heterogeneity among the studies using standard chi-squared tests and the magnitude of heterogeneity was estimated using the I^2 statistic.⁶⁴ In instances of 10 or more studies, we formally assessed for publication bias, whether the distribution of the effect sizes was symmetric with respect to the precision measure, using funnel plots and Egger's linear regression method.^{65,66}

We used stratified analyses and visual inspection of forest plots arranged by effect size and/or meta-regressions (combining all studies included for KQ 2) to examine the effect of a priori-specified primary sources of heterogeneity on effect size: study population, intervention type, intervention intensity (including number of contacts and duration of intervention), length of followup, overall methodologic quality of study, year of publication, country setting (United States vs. other), type of control group, and population risk (including average age, percent smokers, percent with hypertension, percent with dyslipidemia, percent with diabetes, average systolic blood pressure [SBP], average LDL cholesterol, average BMI, medication use). For each of the intermediate health outcomes, we also used meta-regressions to examine whether population, intervention focus, intervention intensity (high vs. not high), publication year, study quality (rated on a 4-point scale), and mean age of the study sample were associated with effect size. We conducted two sets of models when examining intervention by intensity, year, study quality, and age—one controlling for population (using the multiple risk factors population as the

reference group) and one controlling for intervention focus (using the combined healthy diet plus physical activity interventions as the reference group). We performed all analyses using Stata 11.2 (StataCorp, College Station, TX).

Expert Review and Public Comment

A draft research plan was available for public comment from January 29 to February 25, 2013 that included the analytic framework, KQs, and inclusion criteria. We made no substantive changes to our review methods based on comments received. A draft version of this report was reviewed by six invited content experts as well as federal partners from the CDC, Centers for Medicare & Medicaid Services, National Institutes of Health, U.S. Department of Veterans Affairs (VA), and the Military Health Service. Comments received during this process were presented to the USPSTF during its deliberation of the evidence and subsequently addressed, as appropriate, in this final version of the report. Additionally, a full draft report was posted for public comment on the USPSTF's Web site from May 13 to June 9, 2014. We received comments from five unique individuals or organizations. All comments were reviewed and considered. No new substantive issues were brought up during the public comment periods that were not previously considered. No major changes were made to the text in the final report. Minor editorial suggestions/corrections were addressed as appropriate.

USPSTF Involvement

The authors worked with three USPSTF liaisons at key points throughout the review process to refine the inclusion criteria, address methodological decisions on applicable evidence, and resolve issues around the scope of the final evidence synthesis. AHRQ funded this research under a contract to support the work of the USPSTF. AHRQ staff provided oversight for the project and assisted in external review of the draft evidence synthesis.

Chapter 3. Results

Description of Included Studies

We included 74 fair- to good-quality healthy lifestyle counseling trials in persons with cardiovascular risk factors that met our inclusion criteria (**Tables 1 and 2**). Of these 74 included trials, only 16 trials reported health outcomes (KQ 1) (e.g., CVD events, self-reported QOL), 71 trials reported intermediate health outcomes (KQ 2) (e.g., lipid measures, blood pressure, glucose, diabetes incidence, weight measures), 61 trials reported behavioral outcomes (KQ 3) (e.g., objective or self-reported measures of change in diet or physical activity), and 10 trials explicitly reported on harms (or lack thereof) of counseling interventions (KQ 4). We did not identify any additional studies that addressed harms of counseling interventions other than the trials included for KQs 1–3.

Included Populations

We included 17 trials conducted exclusively in persons with dyslipidemia or that included an intervention aim that was primarily focused on reducing cholesterol (**Table 3**).⁶⁷⁻⁸³ We included 15 trials conducted exclusively in persons with hypertension (**Table 4**).^{67,69-87} We included 16 trials aimed at preventing diabetes in persons with impaired fasting glucose or glucose tolerance (**Table 5**).⁸⁸⁻¹⁰³ We included 26 trials in persons selected for any one or a combination of CVD risk factors, most commonly including dyslipidemia, hypertension, elevated glucose (including diabetes), metabolic syndrome, obesity, and smoking (**Table 6**). Most trials ranged from 50 to 1,000 participants. Only one trial had fewer than 50 participants.¹⁰⁴ Seven trials had more than 1,000 participants, including Vitalum,¹⁰⁵ Diabetes Prevention Program (DPP),⁸⁹ Euroaction,¹⁰⁶ Inter99,¹⁰⁷ WISEWOMAN California,¹⁰⁸ Rural Health Promotion Project (RHPP), and the National Exercise Referral Scheme (NERS) trial.¹⁰⁹ The mean age in populations studied ranged from 40.5 to 71 years (interquartile range [IQR], 52.0 to 59.4 years). Nine trials specifically targeted older adults. The mean age in these trials ranged from 64.5 to 71 years. Both men and women were well represented in included trials, most of which included both sexes. Four trials included only women^{82,104,108,110} and five trials included only men.^{75,93,97, 111,112} About one third (k=28) of included trials were conducted in the United States. The remaining trials were conducted in western Europe (k=33), Australia (k=6), Japan (k=3), Canada (k=2), and New Zealand (k=2). Of the trials conducted in the United States, 23 trials reported including nonwhite populations that ranged from 4 to 100 percent. More than one third of participants were nonwhite in 12 of the U.S.-based trials.

The proportion of participants with dyslipidemia at baseline ranged from 5.5 to 100 percent for included trials, where reported, with a range of baseline LDL cholesterol from 105.7 to 202.7 mg/dL. The proportion with hypertension ranged from 0 to 100 percent, with a range of SBP from 123 to 162 mm Hg. In trials including persons with impaired fasting glucose or glucose intolerance, fasting blood glucose at baseline ranged from 93.2 to 110.6 mg/dL. When reported, the proportion of smokers in included trials ranged from 0 to 100 percent. The average BMI in all but two trials^{93,97} ranged from overweight to obese. The median BMI was 29.8 kg/m² (IQR,

28.4 to 31.2 kg/m²). While we excluded trials conducted exclusively in persons with diabetes, many trials included some persons with diabetes, ranging from 3.6 to 45.4 percent.

Trials did not generally restrict or require the use of lipid-, blood pressure-, or glucose-lowering medications. In nine of the 17 trials conducted exclusively in persons with dyslipidemia, however, participants were not allowed to be taking lipid-lowering medications. Three of the 15 trials were conducted exclusively in persons with hypertension who were not allowed to be taking antihypertension medication, while five trials explicitly selected for persons taking them. None of the trials in persons with impaired fasting glucose or glucose tolerance included participants taking medications for glycemic control.

Included Interventions

The 74 trials included 49 diet and exercise counseling intervention arms, 18 diet-only intervention arms, and 10 physical activity intervention arms (**Table 2**). Of the interventions evaluated, only two were low-intensity, 48 were medium-intensity, and 37 were high-intensity interventions (**Tables 7–10**). Medium-intensity interventions had a median number of five contacts (IQR, 3 to 8 contacts), with a median duration of 9 months (IQR, 4 to 11 months). High-intensity interventions had a median number of 16 contacts (IQR, 9 to 31 contacts), with a median duration of 12 months (IQR, 8 to 18 months). The vast majority of interventions relied on face-to-face sessions, either in individual or group sessions (**Appendix E**). Although many interventions used adjunctive telephone contacts, five medium-intensity trials relied solely on telephone and mail contacts to deliver the behavioral counseling.^{67,84,105,113,114} Given the intensity and expertise needed for these interventions, the counseling interventions evaluated are primarily referable from primary care, as opposed to delivered in primary care. Counseling interventions were delivered by dietitians or nutritionists, physiotherapists or exercise professionals/consultants, and/or trained interventionists (e.g., health educators, psychologists, nurses, case managers, life coaches).

Counseling interventions were aimed at promoting knowledge, motivation, and skills for healthy diet and/or increased physical activity (**Appendix E**). Individually-tailored healthy diet counseling included at least one, but most often a combination of messages, including: decreased portion sizes/calories; decreased fat, saturated fat, and cholesterol; decreased salt; increased fruits and vegetables; increased complex carbohydrates and/or fiber; decreased refined sugar; and alcohol in moderation. Individually-tailored physical activity counseling focused on increasing physical activity, some of which included optional supervised exercise sessions, pedometers, and diaries. Counseling interventions, regardless of focus on diet, physical activity, or combined lifestyle messages, included didactic education (i.e., with limited patient interaction) as well as individualized care plans, problem solving skills, and audit and feedback. A few interventions also included financial incentives (including low-cost exercise options) and family/spouse support. Although our review excluded interventions solely aimed at weight loss or weight management, many included trials involved weight loss or weight goals for participants who were overweight. Similarly, although our review excluded interventions solely aimed at smoking cessation, some counseling interventions included smoking cessation counseling when applicable. Some counseling interventions were paired with management algorithms to adjust medications (start, stop, change dosage). The vast majority of trials (k=47)

used usual care as a comparator. Therefore, while we assume that persons in the control group received some sort of counseling, it was not well described in the majority of articles. Twelve trials used a wait-list control, in which participants in the control group likely did not receive active counseling during the trial period. Fourteen trials used minimal intervention as a control, and these trials included counseling that may not be provided as standard of care in most primary care settings (e.g., reminder email prompts to primary care clinicians, substantive nontailored written patient education materials, pedometers, brief annual counseling).

Quality

All trials were rated as fair to good quality. Thirteen trials were excluded for poor quality (**Appendix C**). We included 11 good-quality and 63 fair-quality trials. We rated one trial as good quality for health outcomes (KQ 1), but only fair quality for intermediate health outcomes (KQ 2) because of higher attrition for measurement of intermediate outcomes. In general, the limitations for these fair-quality studies included: lack of reporting of details about randomization; small differences in baseline characteristics between intervention arms; lack of blinding of outcomes assessment (for nonobjective measures); attrition greater than 20 percent, but less than 40 percent; differential attrition between study arms; evidence of attrition bias or lack of details to assess for attrition bias; and lack of reporting on how missing data were handled or having completers-only analyses. Fidelity of, and adherence to, the intervention was not commonly reported.

KQ 1. Do Primary Care–Relevant Behavioral Counseling Interventions for Healthy Diet and/or Physical Activity Improve CVD-Related Health Outcomes in Adults With Known CVD Risk Factors?

Overall Results

Only 16 included trials reported measures of patient health outcomes (**Table 11**). Five of these trials reported CVD events, including mortality.^{89,115-118} Nine of these trials combined lifestyle interventions^{85,86,92,94,95,110,119-121} and two of the physical activity–only trials^{98,122} reported self-reported QOL or depression symptom outcomes. One additional physical activity counseling trial used QOL outcomes (the 36-Item Short-Form Health Survey [SF-36]), but only reported results for selected domains (subscores).¹²³ Overall, there was no reduction in CVD events or mortality at 6 to 79 months across four of five trials reporting these outcomes. Event rates, however, were generally low. One good-quality trial, the Finnish Diabetes Prevention Study, found no difference in CVD events or mortality at the 10-year observational followup from the original trial.¹²⁴ One early good-quality trial, the Risk Factor Intervention Study, was a high-intensity behavioral counseling intervention in conjunction with a protocol to start medication for dyslipidemia or elevated glucose or nicotine replacement therapy for tobacco smoking among Swedish men. This intervention reduced a composite measure of all CVD events compared with usual care at 6.6 years (relative risk [RR], 0.71 [95% CI, 0.51 to 0.99]).¹¹² Overall, combined lifestyle interventions do not appear to improve self-reported depression symptoms (k=4) in

persons with impaired fasting glucose or glucose tolerance at 6 to 12 months.^{85,92,94,95} Findings of benefit on self-reported QOL measures were mixed. While three combined lifestyle counseling interventions appeared to improve selected measures of QOL,^{86,110,119} two combined lifestyle counseling interventions^{120,121} and two physical activity–only counseling interventions^{98,122} showed no benefit on self-reported QOL at 6 to 12 months.

Sparse reporting of both CVD events and self-reported measures of depression symptoms or QOL do not allow for definitive conclusions as to whether or not behavioral counseling interventions can improve patient health outcomes. We did not consider diabetes incidence or changes in CVD risk score as health outcomes. We discuss these outcomes with intermediate health outcomes in KQ 2.

Detailed Results for CVD Events and/or Mortality

Four good-quality trials (n=3,962) of high-intensity combined lifestyle behavioral counseling interventions did not reduce CVD outcomes or mortality (**Table 11; Appendix G Table 1**).^{89,116-118} These event rates were very low, however. DPP (n=2,161) was aimed at preventing diabetes in overweight persons with impaired fasting glucose.⁸⁹ The mean age of participants was 51 years and about one quarter to one third of participants had hypertension or dyslipidemia, respectively. PREMIER (n=304, hypertension subgroup only) was aimed at lowering blood pressure in persons who were not yet taking medications.¹¹⁶ The mean age of participants was 52 years and the mean SBP at baseline was 144 mm Hg. The Trial of Non-pharmacologic Intervention in the Elderly (TONE) (n=975) was aimed at lowering blood pressure in persons who were already taking antihypertension medications; participants were older, with a mean age of 67 years, and the mean SBP at baseline was 128 mm Hg.¹¹⁷ None of these studies included persons with diabetes. PREMIER only had 6 months of followup. While DPP and TONE reported longer-term followup (up to 36 months), they had low CVD event rates at approximately 6 to 15 CVD events per 1,000 person-years. One good-quality trial, the Finnish Diabetes Prevention Study (n=522), was conducted in Finland and evaluated a high-intensity combined lifestyle counseling intervention to prevent diabetes. This trial reported long-term observational followup on mortality and CVD events from the original trial.¹²⁴ At approximately 10 years, the study reported no statistically significant difference in mortality (hazard ratio [HR], 0.57 [95% CI, 0.21 to 1.58]) (2.2 vs. 3.8 deaths per 1,000 person-years in the intervention and control groups, respectively) or CVD events (HR, 1.04 [95% CI, 0.72 to 1.51]) (22.9 vs. 22.0 events per 1,000 person-years in the intervention and control groups, respectively) between the group originally assigned to a high-intensity combined lifestyle intervention to prevent diabetes and the usual care control group.

The Risk Factor Intervention Study (n=508) was also a good-quality trial that evaluated a high-intensity behavioral counseling intervention that reported CVD outcomes, including mortality.¹¹² This trial, however, was conducted in Sweden in the late 1980s and only included men. The mean age of participants was 66 years, all participants had hypertension, the mean SBP was 155 mm Hg, and three quarters of participants also had dyslipidemia (mean LDL cholesterol, 178 mg/dL). Notably, 29 percent of participants were current smokers and 22 percent had diabetes. Eight percent of participants had a previous myocardial infarction (MI). In addition to this population being at much higher risk for CVD events than those in the other four trials, the

intervention included a protocol to start medication for dyslipidemia or elevated glucose or nicotine replacement therapy if counseling was not sufficient. At 6.6 years, 41 persons had died in the intervention group compared with 64 persons in the usual care group (RR, 0.62 [95% CI, 0.42 to 0.92]). The trial reported 63 CVD events (fatal or nonfatal MI or cerebrovascular accident) in the intervention group compared with 84 CVD events in the usual care group (RR, 0.71 [95% CI, 0.51 to 0.99]).¹¹² It is unclear if the higher event rate (presumably due to a sicker population and inclusion of persons with diabetes and prior MI), the addition of medication adjustment to behavioral counseling, or the difference in standard of care for CVD risk reduction in the 1980s led to the difference in beneficial effect on health outcomes seen in this trial.

Detailed Results for Self-Reported Patient Health Outcomes

Four trials (n=893), three fair-quality trials conducted in Australia and Germany and one good-quality trial conducted in the United States, evaluated high-intensity combined lifestyle behavioral interventions (**Table 11**).^{85,92,94,95} These trials reported that the interventions did not reduce self-reported depression symptoms as measured by the Depression Anxiety Stress Scale, Hospital Anxiety and Depression Scale, or Center for Epidemiologic Studies Depression Scale at 6 to 12 months. Although conducted in different countries, all trials included similar populations: middle-aged adults (mean age range, 52 to 65 years) at risk for developing diabetes (mean fasting blood glucose range, 93 to 106 mg/dL). The U.S. trial was conducted in mostly Latina women with a mean BMI of 34 kg/m², which was somewhat higher than in the other three trials.⁹⁴

Five fair-quality trials (n=1,268) evaluated combined lifestyle counseling interventions and showed mixed findings of benefit on self-reported QOL measures, two of which were conducted in the United States.^{86,110,119-121} While PREMIER also reported self-reported QOL measures, these results were not reported for the hypertension subgroup and are not discussed further.¹²⁵ The three fair-quality trials (n=529) evaluating medium- to high-intensity counseling interventions showed greater improvement in self-reported QOL compared with usual care at 6 to 12 months.^{119,120} A small trial (n=63) conducted in Sweden showed a statistically significant difference in health status as measured on a 100-mm Visual Analogue Scale (72.8 vs. 54.5 in the intervention and usual care groups, respectively; p<0.001 at 12 months). This study was conducted by Nilsson and colleagues in 1992 among mostly men with hypertension and a mean age of 56 years.¹¹⁹ A more recent, and much larger, trial (n=640) conducted in France, the Pan European Grid Advanced Stimulation and State Examination, included both men and women with a mean age of 57 years and a mixture of CVD risk factors. This trial showed a small, but statistically significant, change in the physical component score (PCS) of the SF-36: an increase of 2.57 in the intervention group versus a decline of 0.5 in the usual care group at 6 months.¹²⁰ This trial found no difference in results for the mental component score (MCS) of the SF-36. Finally, a recent trial, Live Well Be Well (n=230), evaluated a high-intensity diabetes prevention intervention in a racially diverse U.S. population with impaired fasting glucose.⁸⁶ This trial showed a small, but statistically significant, improvement in QOL as measured by the Psychological Well-Being II scale at 6 and 12 months. However, there were no statistically significant differences between groups at 12 months in other measures, including self-rated health and the Psychological Distress II scale.

Two fair-quality trials (n=739) that evaluated medium- to high-intensity counseling interventions did not show any difference in self-reported QOL measures compared with usual care at 6 to 12 months. A small trial (n=99), the Patient-motivated Health Promotion Program, was conducted in Japanese men and women with a mean age of 64 years. Participants had hypertension or impaired fasting glucose and showed no change in General Health Questionnaire-30 scores at 12 months.¹²¹ A larger trial (n=236), WISEWOMAN North Carolina, was conducted in poor underinsured and uninsured American women. Participants had a mean age of 53 years and a mixture of hypertension, dyslipidemia, diabetes, and obesity. This trial reported no changes in the MCS or PCS of the SF-8 at 6 or 12 months.¹¹⁰

Two fair-quality trials (n=422) evaluated physical activity–only counseling interventions and showed no benefit on self-reported QOL measures.^{98,122} One U.S.-based trial (n=302), the Enhanced Fitness Trial, included men attending a VA hospital center with a mean age of 67 years and impaired fasting glucose. This trial found no improvements in SF-36 scores at 12 months between participants receiving a high-intensity counseling intervention to increase physical activity and those receiving a minimal intervention that included a referral to a physical activity and nutrition program.⁹⁸ A Canadian trial (n=120), the Physical Activity Counseling trial, targeted inactive adults who had CVD risk factors, including hypertension, diabetes, and obesity. The mean age of participants was 47 years. This trial found no improvement in the MCS or PCS of the SF-12 at 6 months between participants receiving a medium-intensity counseling intervention to increase physical activity and those receiving a minimal intervention of a tailored physical activity prescription.¹²²

KQ 2. Do Primary Care–Relevant Behavioral Counseling Interventions for Healthy Diet and/or Physical Activity Improve CVD-Related Intermediate Outcomes in Adults With Known CVD Risk Factors?

Overall Results

Seventy-one of the 74 included trials evaluating diet and/or physical activity counseling interventions reported intermediate health outcomes (**Tables 1 and 2**). Commonly reported intermediate outcomes included: objective lipid measures, blood pressure, glucose, weight, composite cardiovascular risk scores, medication use, and diabetes incidence (**Appendix D Tables 1–9**). Of the 71 trials, only 14 trials could not be included in meta-analyses of intermediate health outcomes, primarily because of limitations in data reporting at the primary study level (e.g., no measure of dispersion).^{69,76,77,97,108,117,120,126-132} Therefore, we focus primarily on results of meta-analyses and discuss discrepancies between meta-analysis findings and trial results that we did not include in quantitative analyses. In a handful of instances, there were minor discrepancies in results presented in the meta-analyses and summary tables because unadjusted values were used in the meta-analyses (if adjusted values could not be used in quantitative pooling) and adjusted results were presented in the summary tables. These differences are noted in the summary tables (**Tables 12–15**).

Medium- to high-intensity diet and physical activity counseling interventions in persons selected for CVD risk factors (dyslipidemia, hypertension, and/or impaired fasting glucose or glucose intolerance) can decrease total cholesterol, LDL cholesterol, blood pressure, fasting glucose, diabetes incidence, and measures of weight (**Appendix D Tables 1–9**). Overall, benefits in these intermediate health outcomes appear to be most robust at 12 to 24 months. The limited number of trials that included longer-term followup limits interpretation of the benefit of findings to after 24 months. Across all trials that reported each specific outcome at 12 to 24 months, behavioral counseling appears to reduce total cholesterol (k=34) by an average of 4.48 mg/dL (95% CI, 6.36 to 2.59), LDL cholesterol (k=25) by 3.43 mg/dL (95% CI, 5.37 to 1.49), SBP (k=31) by 2.03 mm Hg (95% CI, 2.91 to 1.15), diastolic blood pressure (DBP) (k=24) by 1.38 mm Hg (95% CI, 1.92 to 0.84), fasting glucose (k=22) by 2.08 mg/dL (95% CI, 3.29 to 0.88), diabetes incidence (k=8) by an RR of 0.58 (95% CI, 0.37 to 0.89), and measures of weight (k=34) by a pooled mean difference of 0.26, using standardized units (standardized mean difference [SMD], 0.26 [95% CI, 0.35 to 0.16]). However, statistical heterogeneity across all trials for fasting glucose and weight outcomes was very high. Pooled effect sizes were generally similar for medium- versus high-intensity counseling interventions (**Appendix F Figures 1–12**). High-intensity combined lifestyle counseling in persons with impaired fasting glucose or glucose tolerance (k=5) reduces diabetes incidence in the longer term (RR, 0.55 [95% CI, 0.45 to 0.67]; $I^2=27%$). Medium- to high-intensity counseling interventions focusing on dietary changes alone, primarily in persons with dyslipidemia who are not yet taking medications to lower cholesterol, can modestly lower total cholesterol (k=9) by 3.75 mg/dL (95% CI, 6.50 to 1.01; $I^2=24%$) and LDL cholesterol (k=7) by 4.27 mg/dL (95% CI, 7.84 to 0.70; $I^2=40%$) at 12 to 24 months. Both medium- and high-intensity interventions were effective. While high-intensity counseling resulted in slightly larger pooled estimates of total and LDL cholesterol and fasting glucose, the confidence interval estimates for medium- and high-intensity interventions overlapped (**Appendix F Figure 3**). Most physical activity–only counseling interventions were of medium intensity (k=8), although two were of high intensity. While our ability to draw definitive conclusions is limited by the small number of physical activity only–counseling trials (k=10) and heterogeneity (e.g., in populations studied, outcomes measured) among the trials, these types of interventions do not appear to improve intermediate CVD-related outcomes at 12 to 24 months.

The populations targeted and the types of counseling interventions evaluated were the two main a priori–specified explanatory factors for clinical (and statistical) heterogeneity in this body of literature. Populations were defined as selected primarily for having: 1) dyslipidemia, 2) hypertension, 3) impaired fasting glucose or glucose tolerance, or 4) a mixture of CVD risk factors, including dyslipidemia, hypertension, elevated glucose (including diabetes), metabolic syndrome, smoking, and obesity. We categorized interventions as focusing on: 1) both diet and physical activity counseling, 2) diet-only counseling, or 3) physical activity–only counseling. Therefore, we present our results stratified by population (**Tables 16–19**) and intervention type (**Table 20**).

Results in Persons With Dyslipidemia

Seventeen fair- to good-quality counseling trials (n=4,963) selected primarily for persons with dyslipidemia.⁶⁷⁻⁸³ An additional 24 fair- to good-quality trials (n=15,997) selected participants for a mixture of risk factors, including dyslipidemia, and reported intermediate outcome

measures (**Table 12**). Of the 17 trials in persons with dyslipidemia, we rated only one trial⁷² as good quality and all the others as fair quality. For limitations in fair-quality trials, please see the “Quality” section under “Description of Included Studies.” All but three trials conducted in persons selected primarily for dyslipidemia evaluated diet-only counseling. One of these trials was conducted in persons with familial hyperlipidemia (PRO-FIT), one evaluated a telephone counseling intervention (CouPLES [Couples Partnering for Lipid Enhancing Strategies]), and one was an older trial from 1993 (RHPP) that included both diet and physical activity counseling.⁶⁷⁻⁶⁹ The mean age in these trials ranged from 40.5 to 71 years (**Table 3**). Most trials included a fair representation of both men and women, except for three trials in mostly (or entirely) men^{67,75,80} and one trial in entirely women.⁸² Average baseline total and LDL cholesterol ranged from 233 to 282 mg/dL and from 156 to 200 mg/dL, respectively, in persons who were not taking lipid-lowering medications. The majority of trials (k=13) evaluated medium-intensity interventions. All but one trial used a usual care, wait list, or attention control.⁶⁷ In this trial, CouPLES, the control group physicians received email reminders emphasizing the use of lipid-lowering medications. All but three trials (earlier trials from the 1990s) were included in the meta-analyses.^{69,76,77} For a similar description of trials in populations with mixed risk factors, please see the section below, “Results in Persons With Mixed CVD Risk Factors.”

The majority of trials conducted in persons selected primarily for dyslipidemia reported outcome measures of total (k=9) and LDL cholesterol (k=8) at 12 to 24 months (**Table 16**). Fewer trials (k=5) reported outcomes at less than 12 months. No trials reported longer-term outcomes (>24 months). At 12 to 24 months, medium- to high-intensity diet-only counseling trials reduced total (k=9) and LDL cholesterol (k=8) by 3.31 mg/dL (95% CI, 5.98 to 0.64) and 3.93 mg/dL (95% CI, 7.23 to 0.62), respectively (**Figures 2 and 3**). Because most trials included persons who had not yet started medications, these results are most applicable to persons who are not yet taking lipid-lowering medication. Looking more broadly across all types of medium- to high-intensity interventions in persons selected for dyslipidemia or a mixture of CVD risk factors, counseling interventions reduced total (k=22) and LDL cholesterol (k=17) by 5.11 mg/dL (95% CI, 7.77 to 2.45) and 3.74 mg/dL (95% CI, 6.39 to 1.09), respectively (**Figures 4 and 5**), at 12 to 24 months. The statistical heterogeneity is much higher in these combined pooled analyses, which reflects the greater clinical heterogeneity in population and intervention characteristics. High-intensity counseling resulted in slightly larger pooled estimates of total and LDL cholesterol, but results were not statistically significantly different from effects of medium-intensity counseling (**Appendix F Figures 1 and 3**). Two trials in persons explicitly with dyslipidemia^{76,77} and three trials in mixed CVD risk populations reporting lipid outcomes^{120,129,130} that could not be included in the meta-analyses only reported short-term (<12 months) outcomes. We could not include one fair-quality trial in the meta-analyses, WISEWOMAN California (n=1,093), because of data limitations. This study found no statistically significant reduction in total cholesterol between persons receiving a high-intensity combined lifestyle counseling intervention and usual care at 12 months. The baseline total cholesterol in this population, however, was not elevated (mean, 198.1 mg/dL).¹⁰⁸ We could not include one fair-quality trial in the meta-analyses, RHPP (n=1,197), because of data limitations. This study, however, found no statistically significant difference in total cholesterol between persons receiving a medium-intensity combined lifestyle counseling intervention and usual care at 30 months.⁶⁹ Limited available data prevent any definitive conclusions about the efficacy of lifestyle counseling interventions beyond 24 months.

Fewer trials reported HDL cholesterol and triglycerides as outcome measures (**Table 16**). The trials that did report HDL cholesterol found no statistically significant effects. While there were statistically significant reductions in triglycerides, there was evidence of publication bias due to small-study effects. Many studies also reported weight measures (i.e., weight and/or BMI) as an outcome. Across all trials in persons with dyslipidemia or a mixture of CVD risk factors, medium- to high-intensity counseling can reduce measures of weight (k=18) by an SMD of 0.22 (95% CI, 0.35 to 0.10) (**Figure 6**). The statistical heterogeneity of this pooled analysis, however, was very high. Two earlier trials from the 1990s appear to be outliers, which contributes to the statistical heterogeneity.^{71,80}

Results in Persons With Hypertension

Fourteen (n=4,990) of 15 fair- to good-quality trials^{67,69-87} in persons selected primarily for hypertension and 24 fair- to good-quality trials (n=15,997) in persons selected for a mixture of risk factors, including hypertension, reported intermediate outcome measures (**Table 13**). Of the 13 trials in persons with hypertension, only two trials were of good quality^{116,117} and the others were fair-quality. For limitations in fair-quality trials, please see the “Quality” section under “Description of Included Studies.” Two trials had multiple intervention arms evaluating diet or physical activity only versus combined lifestyle counseling.^{117,128} Therefore, we included a total of 13 combined diet and physical activity counseling interventions, three diet-only counseling interventions, and two physical activity–only counseling interventions. The mean age in these trials ranged from 51 to 67 years and most included an even representation of both men and women, except for two trials in mostly (or entirely) men^{111,113} and one trial in entirely women.¹⁰⁴ The majority of trials included persons who were taking antihypertension medications. Only three trials explicitly targeted persons who were not yet taking medications.^{111,116,127} Average baseline SBP and DBP ranged from 127 to 162 mm Hg and from 71 to 96 mm Hg, respectively, in persons taking medications and averaged approximately 144/87 mm Hg in persons not yet taking them (**Table 4**). Nine trials evaluated medium-intensity^{84,104,105,111,113, 128,133-135} and six trials evaluated high-intensity^{116,117,126, 127,136,137} counseling interventions. Most trials used a usual care or wait list control in which participants were assumed to receive usual care as a comparator group, except for four trials in which the control group received minimal interventions.^{76,113,126,134} Four trials could not be included in the meta-analyses because of limitations in how data were reported in the primary studies.^{117,126-128} For a similar description of trials in populations with mixed risk factors, please see the section below, “Results in Persons With Mixed CVD Risk Factors.”

Medium- to high-intensity diet and physical activity counseling interventions resulted in reductions in blood pressure up to 12 to 24 months. Only three trials (two included in the meta-analyses) reported outcomes beyond 24 months. At 12 to 24 months, counseling trials conducted exclusively in persons with hypertension reduced SBP (k=6) and DBP (k=6) by 2.29 mm Hg (95% CI, 3.82 to 0.76) and 1.22 mm Hg (95% CI, 2.53 to -0.08), respectively (**Figures 7–8**). While point estimates of reductions in SBP were greatest in the short term (<12 months), the confidence intervals overlap with estimates at 12 to 24 months. Trials included a range of participants who were and were not taking medications. Therefore, these findings are applicable to both persons who are and are not yet taking medication. Looking more broadly across persons selected explicitly for hypertension and a mixture of CVD risk factors, medium- to high-intensity

counseling interventions reduced SBP (k=20) and DBP (k=16) by 1.99 mm Hg (95% CI, 3.15 to 0.83) and 1.23 mm Hg (95% CI, 1.91 to 0.56), respectively (**Figures 9–10**), at 12 to 24 months. Pooled effect sizes were similar for medium- and high-intensity counseling interventions (**Appendix F Figures 5 and 7**).

Of the seven trials that were not included in the meta-analyses (k=4 for hypertension, k=3 for mixed CVD risk factors), four trials only reported outcomes at 6 months.^{120,127,128,130} One fair-quality trial, WISEWOMAN California (n=1,093), could not be included in the meta-analyses because of data limitations. This trial found a statistically significant reduction in SBP between persons receiving a high-intensity combined lifestyle counseling intervention and usual care at 12 months. These findings are consistent with findings from meta-analyses.¹⁰⁸ One fair-quality trial (n=337) conducted by Migneault and colleagues found no statistically significant reduction in SBP or DBP between a high-intensity combined lifestyle counseling intervention group and a minimal intervention control group (who received a 75-page resource manual in addition to a pedometer and scale) at 8 to 12 months.¹²⁶ The nonstatistically significant reduction in SBP and DBP in this trial was consistent with the magnitude of results of trials included in the meta-analyses. Another good-quality trial, TONE (n=975), did not report SBP or DBP. Instead, this trial used a composite measure (proportion of participants free of CVD events, hypertension, or medications)¹¹⁷ and found that a high-intensity diet and physical activity counseling intervention increased the proportion of persons free of CVD events, hypertension, or medications compared with a usual care control group at 30 months (HR, 0.69 [95% CI, 0.59 to 0.81]). Limited available data prevent us from drawing definitive conclusions about the efficacy of lifestyle counseling interventions beyond 24 months.

Fewer trials reported lipid or glucose outcome measures (**Table 17**). Mostly combined diet and physical activity counseling interventions found reduced total (k=4) and LDL cholesterol (k=2) in persons with hypertension, as well as total (k=17) and LDL cholesterol (k=11) in persons with hypertension or a mixture of CVD risk factors. The magnitude of effect on lipid reduction was similar to that seen in persons who explicitly had dyslipidemia. Many studies also reported weight measures as an outcome. Across all trials in persons with hypertension or a mixture of CVD risk factors, medium- to high-intensity counseling can reduce measures of weight (k=16) by an SMD of 0.21 (95% CI, 0.34 to 0.08) (**Figure 11**). The statistical heterogeneity of this pooled analysis, however, is very high. Again, the effect size of the reduction in weight measures is similar to that seen in persons explicitly with dyslipidemia. One trial in particular, the Activity Diet and Blood Pressure Trial (ADAPT) (n=241), appears to be an outlier that contributes to the statistical heterogeneity.¹³⁸

Other outcomes that were not included in meta-analyses were medication use and composite CVD risk scores (**Tables 13 and 15**). Three trials conducted exclusively in persons with hypertension (n=1,520) sought to reduce the use of antihypertension medication.^{116,117,138} Two good-quality trials conducted in the United States, PREMIER (n=304, hypertension subgroup only) and TONE (n=975), showed a statistically significant increase in the proportion of persons who were free of medication at 18 to 36 months.^{116,117} Participants in the PREMIER trial were not taking antihypertension medications and all participants in the TONE trial were taking them. In PREMIER, 21 percent of persons in the high-intensity counseling intervention group versus 41 percent of persons in the usual care control group were taking antihypertension medications at

18 months.¹¹⁶ In TONE, the mean interval from intervention start to withdrawal of medications was about 3 months. At 36 months, 93.2 percent of persons in the high-intensity combined diet and physical activity counseling intervention group versus 86.8 percent of persons in the control group had stopped taking antihypertension medications. One fair-quality trial, ADAPT (n=241), included participants who were taking antihypertension medications and found no difference in medication use requirement between the medium-intensity counseling intervention group and usual care control group at 36 months.¹³⁸

Twelve of the included trials (n=6,781) used a composite CVD risk score as an outcome measure.^{100,102,103,108,116,120,123,132,133,138-140} Two of these trials were conducted exclusively in hypertensive populations^{116,138} and 10 were conducted in populations selected for a mixture of CVD risk factors.^{100,102,103,108,120,123,132,133,139,140} Overall, there was generally no difference in 10-year CVD risk as measured by the Framingham Risk Score or Systematic Coronary Risk Evaluation at 6 to 36 months. Two trials found a very small, albeit statistically significant, change in 10-year risk at 12 months.^{133,140} One trial, Improving Patient Adherence to Lifestyle Advice (n=615), was conducted in the Netherlands. This trial found a difference of 0.9 percent (p=0.023) in 10-year risk using the Systematic Coronary Risk Evaluation between a medium-intensity combined lifestyle counseling intervention group and usual care group.¹³³ The baseline 10-year CVD risk was low in this population at approximately 5 percent. One good-quality trial (n=315) conducted by Wister and colleagues in Canada found a 1.8 percent difference (p<0.05) in 10-year risk using the Framingham Risk Score between a medium-intensity combined lifestyle counseling intervention group and usual care group.¹⁴⁰ The baseline 10-year CVD risk was slightly higher in this trial population at 11 percent.

Results in Persons With Impaired Fasting Glucose or Glucose Tolerance

Sixteen fair- to good-quality counseling trials (n=5,883) in persons selected primarily for impaired fasting glucose or glucose intolerance⁸⁸⁻¹⁰³ and an additional 24 fair- to good-quality trials (n=15,997) in persons selected for a mixture of risk factors, including elevated glucose or metabolic syndrome, reported intermediate outcome measures (**Table 14**). Of the 16 trials in persons with impaired fasting glucose or glucose intolerance, five trials were good-quality,^{86,87,89,94,118} and the others were all rated as fair quality. For limitations in fair-quality trials, please see the “Quality” section under “Description of Included Studies.” The majority of trials (k=13) were combined diet and physical activity counseling trials; only one trial was diet-only counseling and two trials were physical activity–only counseling. The mean age in these trials ranged from 51 to 67 years (**Table 5**). Most trials had an even representation of both men and women, except for three trials in mostly (or entirely) men.^{93,97,98} Average baseline fasting blood glucose ranged from approximately 94 to 111 mg/dL. Measures of glucose tolerance (1- or 2-hour) and hemoglobin A1c were less commonly reported. None of the trials included participants who were taking glucose-lowering medications at trial entry. In general, the mean BMI ranged from 29 to 34 kg/m². Both trials conducted in Japanese men had a mean baseline BMI of 24 kg/m².^{93,97} The majority of trials (k=13) evaluated high-intensity interventions, two trials evaluated medium-intensity interventions, and one trial evaluated a low-intensity intervention. The medium-intensity combined lifestyle counseling intervention had 12 contacts over 24 months. The other medium-intensity intervention was a physical activity–only counseling intervention with only

three contacts over 6 months. All trials used a usual care or wait list control in which participants were assumed to receive usual care as a comparator group, except for three trials that used minimal intervention control groups.^{89,93,98} All but one trial was included in the meta-analyses.⁹⁷ This trial was quite different from the others in that it was the only low-intensity trial included and the only diet-only counseling intervention in this population. In addition, this trial was conducted in persons who were not overweight. For a similar description of trials in populations with mixed risk factors, please see the section below, “Results in Persons With Mixed CVD Risk Factors.”

The majority of trials in persons with impaired fasting glucose or glucose tolerance reported outcome measures of diabetes incidence (k=11) and fasting blood glucose (k=13) at 12 months or greater (**Table 14**). At 12 to 24 months, medium- to high-intensity (mostly high-intensity) counseling trials (k=6) reduced diabetes incidence by an average of 35 percent (RR, 0.65 [95% CI, 0.42 to 1.02]), albeit not statistically significant (**Table 18**). At longer-term followup greater than 24 months, high-intensity combined lifestyle interventions (k=5) reduced diabetes incidence by an average of 65 percent (RR, 0.55 [95% CI, 0.46 to 0.67]) (**Figure 12**). These findings were similar when the three trials in populations selected for mixed CVD risk factors that also reported diabetes incidence as an outcome were added, and results were statistically significant at both intermediate and long-term followup, with a reduction of diabetes incidence by an RR of 0.58 (95% CI, 0.37 to 0.89) at 12 to 24 months (k=8) and 0.61 (95% CI, 0.46 to 0.79) at greater than 24 months (k=6) (**Figure 13**). Meta-analyses for fasting glucose outcomes support the findings of a reduction in progression to diabetes. While medium- to high-intensity counseling interventions in persons with impaired fasting glucose or glucose tolerance (k=11) reduced fasting glucose by 2.05 mg/dL (95% CI, 3.86 to 0.24) at 12 to 24 months (**Figure 14**), the statistical heterogeneity is very high. In addition, there are a limited number of trials that report fasting glucose outcomes at greater than 24 months (**Table 18**).

Lipid and blood pressure outcomes were not as commonly reported (**Table 18**). Nonetheless, pooled results for these outcomes are generally consistent with findings in other populations. Many studies, however, also reported weight measures as an outcome. Across all trials in persons with impaired fasting glucose or glucose tolerance or a mixture of CVD risk factors, medium- to high-intensity counseling reduced measures of weight (k=24) by an SMD of 0.21 (95% CI, 0.29 to 0.13), similar to the magnitude of reduction seen in other included populations (**Table 18**). The statistical heterogeneity of this pooled analysis, however, is very high.

Results in Persons With Mixed Cardiovascular Risk Factors

Of the total 26 trials conducted in populations that were selected for a mixture of cardiovascular risk factors, 24 fair- to good-quality trials (n=15,997) reported intermediate outcome measures (**Table 15**). Only three of these trials were of good quality,¹³⁹⁻¹⁴¹ however, and the remaining trials were all rated as fair quality. The majority of these trials (k=20) evaluated combined diet and physical activity counseling interventions, although six trials evaluated physical activity-only counseling interventions. The mean age in these trials ranged from 47 to 68 years and most trials included a fair representation of both men and women, except for one early trial exclusively in men¹¹² and two trials entirely in women (**Table 6**).^{108,110} The proportion of persons with hypertension ranged from 9 to 100 percent, with an average SBP of 125 to 158 mm Hg and

DBP of 73 to 91 mm Hg. The proportion of persons with dyslipidemia ranged from 13 to 88 percent, with an average baseline total cholesterol of 185 to 259 mg/dL and LDL cholesterol of 112 to 178 mg/dL. The proportion of persons with impaired fasting glucose or glucose tolerance was not commonly reported. The proportion of persons with diabetes ranged from 0 to 45 percent. The baseline fasting glucose ranged from 93 to 148 mg/dL. The majority of persons in all trials had an average BMI that identified them as overweight to obese. The majority of trials (k=17) evaluated medium-intensity interventions. While most trials used usual care or a wait list control as a comparator group, five trials used a minimal intervention as the control group.^{100,102,107,114,122} Five trials were not included in the meta-analyses because of limitations in reporting of outcome data in the primary studies.^{108,120,129-131}

Outcomes in trials that selected persons based on any number of CVD risk factors are discussed in conjunction with other populations. Please see the above sections, “Results in Persons With Dyslipidemia,” “Results in Persons With Hypertension,” and “Results in Persons With Impaired Fasting Glucose or Glucose Tolerance.”

Results by Intervention Type

The majority of included trials evaluated combined lifestyle interventions with messages to improve diet and increase physical activity (49 intervention arms). Eighteen trials included counseling interventions that focused on diet alone, 14 of which were conducted in persons primarily selected for dyslipidemia, three in persons selected for hypertension, and only one in persons selected for impaired fasting glucose. Only 10 trials evaluated interventions that focused on increasing physical activity alone (**Table 2**). As a result, the findings of benefit on intermediate health outcomes are most robust for combined lifestyle counseling (**Table 20**). Medium- to high-intensity combined lifestyle counseling interventions reduced total cholesterol (k=22) (5.43 mg/dL [95% CI, 7.97 to 2.89]), LDL cholesterol (k=17) (3.69 mg/dL [95% CI, 5.98 to 1.40]), and triglycerides (k=10) (8.33 mg/dL [95% CI, 13.80 to 2.86]) and increased HDL cholesterol (k=14) (0.98 mg/dL [95% CI, 0.25 to 1.70]) at 12 to 24 months in persons selected for dyslipidemia or any number of CVD risk factors (**Figures 16 and 17; Table 20**). Very few trials, however, reported followup after 24 months and the reported effects generally did not seem to last at longer-term followup. Medium- to high-intensity diet-only counseling interventions also reduced total cholesterol (k=9) (3.75 mg/dL [95% CI, 6.50 to 1.01]), LDL cholesterol (k=7) (4.27 mg/dL [95% CI, 7.84 to 0.70]), and triglycerides (k=3) (17.86 mg/dL [95% CI, 33.10 to 2.62]). While the reduction in total cholesterol for diet-only counseling interventions may be smaller than for combined lifestyle interventions, the reduction in LDL cholesterol for these interventions appeared to be the same as for combined lifestyle interventions. None of these trials reported longer-term followup. Overall, while high-intensity counseling resulted in slightly larger pooled estimates of total and LDL cholesterol, confidence interval estimates were overlapping (**Appendix F Figures 1 and 3**).

Combined lifestyle interventions also reduced blood pressure, glucose, diabetes incidence, and measures of weight at both intermediate and longer-term followup. Medium- to high-intensity combined lifestyle counseling interventions reduced SBP (k=27) (2.06 mm Hg [95% CI, 3.03 to 1.08]) and DBP (k=21) (1.30 mm Hg [95% CI, 1.93 to 0.68]). These trials also reduced fasting glucose (k=18) (1.86 mg/dL [95% CI, 3.24 to 0.49]), diabetes incidence (k=6) (RR, 0.54 [95%

CI, 0.34 to 0.88]), and measures of weight (k=25) (SMD, 0.24 [95% CI, 0.35 to 0.14]) at 12 to 24 months in persons selected for CVD risk factors (**Figures 18–21**). Pooled effect sizes for blood pressure, glucose, and measures of weight were similar for medium- versus high-intensity counseling interventions (**Appendix F**). Trials reporting a reduction in diabetes incidence were mostly high-intensity counseling interventions. While fewer trials reported followup after 24 months, reductions in these outcomes persisted at longer-term followup. Trials evaluating diet-only counseling interventions did not commonly measure other intermediate health outcomes.

The included evidence base (k=10) for physical activity–only counseling interventions is much more sparse and less convincing. The majority of these interventions were medium-intensity (k=8), as opposed to high-intensity (k=2) interventions. Four trials were designed to specifically target older adults.^{98,104,123,130} Six of the 10 trials were conducted in populations with mixed CVD risk factors, two were conducted in persons explicitly with impaired fasting glucose, and two were conducted in persons with hypertension. Therefore, the reported outcome measures varied across these trials and pooled analyses for each outcome included few studies, in general. Two fair-quality trials (n=232) only reported short-term outcomes at 6 months and both trials evaluated medium-intensity counseling interventions in persons selected for hypertension.^{104,128} One very small trial (n=24) in women showed a small, but statistically significant, improvement in SBP.¹⁰⁴ Another trial (n=208) conducted in both men and women, however, found no change in SBP or DBP (**Table 13**).¹²⁸ Two fair-quality trials (n=400) were conducted in older adults with impaired fasting glucose.^{98,99} Neither of these trials found a benefit in lipids, glucose, or measures of weight at 12 to 24 months. Finally, six trials were conducted in persons selected for a mixture of CVD risk factors, five of which reported intermediate outcome measures.^{122,123,130,131,141} Four fair-quality trials (n=1,955) reported no changes in short-term (6 to 12 months) intermediate health outcomes (including lipids, glucose, and measures of weight).^{122,123,130,131} One good-quality trial (n=101) conducted by Kallings and colleagues that evaluated a medium-intensity counseling intervention aimed at Swedish older adults found a very small, but statistically significant, benefit on total cholesterol, hemoglobin A1c, and measures of weight. However, this trial did not find an effect on measures of blood pressure or LDL cholesterol.¹⁴¹ Given the limited number of trials and clinical heterogeneity among populations, interventions, and outcomes measured, it is still unclear if medium- or high-intensity counseling interventions aimed at increasing physical activity alone can improve lipids, blood pressure, glucose, and measures of weight in persons with CVD risk factors.

Exploration of Heterogeneity

Our review purposefully includes a wide range of healthy lifestyle counseling trials to improve cardiovascular health published over the past two decades. The main dimensions of clinical heterogeneity included variation in populations studied, interventions evaluated, and study characteristics (including outcomes measured). We a priori specified the major dimensions of heterogeneity and present results stratified by populations targeted and outcomes measured (e.g., trials targeting persons with dyslipidemia generally measured lipid outcomes), as well as stratified by intervention type (i.e., combined lifestyle, diet only, physical activity only). We used exploratory meta-regressions and visual inspection of forest plots to examine if other important a priori–specified variables influenced study effects. Based on this preliminary exploration of heterogeneity, we performed meta-regressions on lipids (total and LDL

cholesterol, triglycerides), blood pressure (SBP and DBP), fasting glucose, and measures of weight outcomes using all data available from the 57 trials included in the meta-analyses. None of the factors we examined appeared to consistently influence effect size across all outcomes. Year of publication appeared to explain some statistical heterogeneity for effects on LDL cholesterol, blood pressure (SBP and DBP), and weight, such that more recent studies had smaller effects on LDL, blood pressure, and weight reduction than earlier studies. High-intensity interventions appeared to explain some statistical heterogeneity for effects on LDL cholesterol (but not on other outcomes), such that higher-intensity interventions had greater LDL cholesterol reduction compared with less intensive interventions. Finally, study quality appeared to explain some statistical heterogeneity for effects on SBP and triglycerides, but not for other outcomes. That is, better-quality studies had smaller effects than studies with more risk for bias. Overall, the differences in effect sizes, as modified by these variables, were very small and likely not clinically significant.

We also assessed if trials targeting specific a priori subpopulations or that included subgroup analyses of these populations showed similar or differential findings of benefit on intermediate health outcomes. In general, there were a limited number of trials that included subgroup analyses by sex, age, or race/ethnicity. Nonetheless, we believe our findings are broadly applicable to men and women, middle- and older-aged adults, as well as nonwhite persons, based on available evidence and a body of evidence that includes an adequate representation of these populations. Nine trials were conducted in men only (or nearly all men)^{67,75,80,93,97,98,111-113} and four trials were conducted in women only.^{82,104,108,110} Direct comparisons of results among these trials are difficult because of the differences in population characteristics (other than sex), interventions, outcomes, and lengths of followup across these studies. Only five of the included studies reported results for intermediate health outcomes stratified by sex.^{71,87,89,142,143} There was no difference in benefit on reduction of cholesterol or diabetes incidence between men and women in the Diet and Exercise for Elevated Risk trial (n=189), which evaluated a high-intensity diet-only counseling intervention to reduce cholesterol, or in DPP (n=2,161), which evaluated a high-intensity combined lifestyle counseling intervention to prevent diabetes.^{71,89} ADAPT (n=241) evaluated a medium-intensity combined lifestyle counseling intervention to reduce blood pressure and demonstrated some differences between sexes at 4 months. These differences, however, did not persist at 12 months. Additionally, there was no statistically significant benefit in blood pressure reduction in the intervention group compared with the control group for either men or women at 36 months.¹⁴² One good-quality trial, E-LITE (Evaluation of Lifestyle Interventions to Treat Elevated Cardiometabolic Risk in Primary Care) (n=241), which evaluated a high-intensity combined lifestyle intervention in persons with impaired fasting glucose or metabolic syndrome, found statistically significant weight loss for men, but not women, at 15 months.⁸⁷ Subgroup analyses by sex for other measured intermediate health outcomes (i.e., blood pressure, lipids, fasting blood glucose) were not reported. PREMIER (n=810) evaluated a high-intensity combined lifestyle intervention in persons with prehypertension and hypertension. Subgroup analyses for PREMIER did not report findings separately for persons with hypertension only. Nonetheless, blood pressure reductions at 6 months were greater for black men compared with black women, but no sex differences were noted for whites.¹⁴³

Included trials generally included populations of middle-aged adults that accurately reflect the distribution of CVD risk factors in the general population. Overall, we did not find a large

variation in mean ages across studies, which ranged from 40 to 71 years. Nine trials specifically targeted older adults or the average mean age of the population was 65 years or older.^{69,98,99,112,113,117,127,130,141} Although direct comparison across trials targeting older adults and those with younger mean ages is difficult because of clinical heterogeneity among trials, the high-intensity combined lifestyle counseling interventions in older adults did improve intermediate health outcomes similar to those in middle-aged adults. Physical activity–only counseling interventions targeting older adults generally (except for one trial conducted by Kallings and colleagues) did not improve intermediate health outcomes, similar to the results of studies conducted in middle-aged adults. Two trials included subgroup analyses that compared older adults with middle-aged adults.^{89,123} DPP, for example, evaluated a high-intensity combined lifestyle intervention to prevent diabetes and found no statistically significant interaction for age (25 to 44 years, 45 to 59 years, and 60 years or older) on reduction of diabetes incidence between the intervention and control groups.⁸⁹ The Green Prescription Programme, which evaluated a medium-intensity physical activity–only counseling intervention, found no significant difference between younger and older participants (ages 65 to 79 years) and generally found no statistically significant differences between intervention and control groups for blood pressure outcomes.¹²³

Of the trials conducted in the United States, 20 trials were conducted in populations that included between 4.4 and 100 percent nonwhite persons.^{67,72-74,81,82,89,98,108,110,113,117,123,126,127,129,135,136} Two trials explicitly targeted Latino Americans^{94,108} and two trials explicitly targeted black Americans.^{126,135} DPP (45% nonwhite participants) conducted post-hoc subgroup analyses by race/ethnicity and found no statistically significant interaction on diabetes incidence.⁸⁹ PREMIER (34% black participants) also conducted subgroup analyses, although they were performed on the entire trial population (including persons with prehypertension). Nonetheless, subgroup analyses showed the greatest blood pressure reductions at 6 months for black men, followed by whites (men and women), and the smallest blood pressure reductions for black women.¹⁴³

Publication Bias

For quantitative analyses, we assessed for publication bias using funnel plots and Egger’s test. We found no evidence for significant publication bias except for triglyceride outcomes (Egger’s test $p=0.02$). Therefore, the findings of benefit on reductions in triglycerides for counseling interventions should be interpreted with caution, as the true effects are likely less optimistic than our estimated effects. In general, one should interpret any findings for outcomes with only a very limited number of trials (i.e., only a small representation of included studies reported a certain outcome), with caution because of possible selective reporting of that outcome and limited reproduction of the specific outcome effect across trials.

KQ 3. Do Primary Care–Relevant Behavioral Counseling Interventions for Healthy Diet and/or Physical Activity Improve Diet and Physical Activity Behavioral Outcomes in Adults With Known CVD Risk Factors?

Overall Results

Sixty-one of the included trials reported behavioral outcomes (**Tables 1 and 2**). Three of these trials reported only behavioral outcomes (KQ 3) and did not report intermediate health outcomes (KQ 2).^{105,109,114} Overall, objectively measured and self-reported changes in dietary intake and physical activity were concordant with intermediate outcome findings (**Tables 16–19**). In several instances in which trials did not find any benefit in intermediate health outcomes, trials demonstrated statistically significant improvements in dietary intake (e.g., fat, saturated fat, fruit and vegetable, total energy) and various measures of self-reported physical activity in the short and intermediate term. In selected trials conducted in persons who were already taking medications to lower cholesterol or blood pressure, counseling interventions appeared to improve dietary intake (e.g., sodium, fat, saturated fat, fruit and vegetable, total energy) and various measures of self-reported physical activity despite a lack of benefit on lipid measures or blood pressure. Many physical activity–only counseling trials only reported short-term outcomes. Four of five trials that reported behavioral outcomes at 12 to 24 months found statistically significant improvements in self-reported physical activity. We did not conduct quantitative pooled analyses because of sparse reporting of objectively measured behavior change (e.g., urinary sodium, VO₂max) and the heterogeneity in self-reported measures of behavior change. Given the robust and consistent findings of benefit on intermediate health outcomes, our summary of results for this question focuses on discrepant or added information that behavioral outcomes provided.

Detailed Results for Behavioral Outcomes

In trials targeting persons with dyslipidemia, all but two trials^{68,76} that reported on dietary intake of fat and/or saturated fat found a statistically significant decrease in consumption at 6 to 24 months, even in trials that did not find a statistically significant benefit on total or LDL cholesterol (**Table 21; Appendix G Table 2**). Only two trials targeting persons with dyslipidemia included those who were already taking lipid-lowering medications,^{67,68} which may make it more difficult to detect an improvement in serum lipid measurements (e.g., total or LDL cholesterol). One fair-quality trial, CouPLES (n=255), was conducted in a VA population in which approximately 46 percent were already taking lipid-lowering medications, and evaluated a medium-intensity combined lifestyle telephone counseling intervention.⁶⁷ At 11 months, although there were no statistically significant differences in medication use or LDL cholesterol, the intervention group reported statistically significant improvements in fat (approximately 11 g fewer per day) and saturated fat (approximately 4 g fewer per day) intake, as well as total energy intake (approximately 200 kcal fewer per day). In another fair-quality trial, PRO-FIT (n=340), Dutch persons with confirmed familial hyperlipidemia, 69 percent of whom were taking lipid-lowering medications, were randomized to receive a medium-intensity combined lifestyle intervention.⁶⁸ At 12 months, there were no statistically significant differences in saturated fat, fruit, or vegetable intake, as well as no statistically significant differences in intermediate health outcomes between those who received counseling and those who received usual care. The findings of improvement in dietary and physical activity outcomes were consistent with intermediate health outcomes in trials targeting persons with hypertension. In trials with no statistically significant benefit on blood pressure outcomes, these trials still found improvements in urinary sodium and self-reported dietary intake (including fat, saturated fat, and fruit/vegetable) and self-reported physical activity at 6 to 24 months (**Table 22; Appendix G**

Table 2). Five of these trials (n=2,335) evaluated medium- to high-intensity counseling interventions exclusively in persons taking antihypertension medications.^{117,126,128,136, 138} Four of the five trials reported no difference in blood pressure and one trial did not report blood pressure outcomes.¹¹⁷ All of the four trials (n=1,698) that reported urinary sodium found a statistically significant decrease in urinary sodium at 6 to 36 months.^{117,128,136,138} Two (n=449) of the four trials that reported physical activity change showed a small, but statistically significant, increase in physical activity (approximately 40 minutes more per week) at 6 and 36 months.^{128,138} Two trials (n=515) also reported other measures of dietary intake and found small, but statistically significant, improvements in saturated fat and fruit and/or vegetable intake at 18 and 36 months.^{136,138} One trial only reported behavioral outcomes.¹⁰⁵ This fair-quality trial conducted in the Netherlands (n=1,629) evaluated low- and medium-intensity mailed and/or telephone interventions with diet and physical activity counseling. This trial found that the medium-intensity telephone intervention (with or without mailed component) improved both physical activity (approximately 50 minutes more per week) and fruit/vegetable (approximately 0.25 more servings per day) intake at 18 months.

Trials targeting persons with impaired fasting glucose or glucose tolerance found improvements in behavioral change, which is consistent with findings of benefit on intermediate health outcomes (**Table 23; Appendix G Table 2**). Seven trials (n=2,127) without consistent statistically significant improvements in intermediate outcomes show that counseling interventions of any intensity could improve self-reported behavioral outcomes.^{85,86,88,92,97,99} All of the five trials (n=1,727) that reported dietary intake showed a small, but statistically significant, improvement in diet (using different measures, including fat, saturated fat, fiber, energy, and a composite score) at 6 to 18 months.^{85,86,88,92,97} Three (n=1,325) of the six trials that reported physical activity showed a statistically significant improvement in physical activity (using different measures, including total physical activity [minutes/week], percent meeting physical activity goal of 150 minutes per week, and moderate to vigorous physical activity [MET/minutes-week]).^{88,98,99}

In trials in persons selected for a combination of risk factors, findings of behavioral change were again consistent with findings of benefit on intermediate health outcomes (**Table 24; Appendix G Table 2**). Eight medium- to high-intensity counseling trials found no consistent statistically significant benefit on intermediate or behavioral outcomes. Five of these trials evaluated a combined lifestyle counseling intervention (n=1,829) and three were physical activity–only counseling trials (n=1,077).^{86,100,102,122,130,131,139,144} Six medium- to high-intensity counseling trials, five combined lifestyle trials (n=6,681), and one physical activity–only counseling trial (n=878) found no consistent statistically significant benefit on intermediate health outcomes, but demonstrated improvement in self-reported diet and/or physical activity behaviors. The physical activity–only trial, the Green Prescription Programme, reported improvement in diet (e.g., total energy, unsaturated fat to fat ratio, fish intake, meals per day with a serving of vegetables, and a composite diet score) and physical activity (e.g., total energy expenditure, leisure time physical activity, minutes per week of moderate to vigorous activity, meeting recommended physical activity levels, and steps per day) behaviors.¹²³ In the five trials (n=6,681) reporting dietary outcome measures (including saturated fat to fat ratio, meeting fruit and vegetable intake recommendations, portions of fruits and vegetables per day, vegetables per day, and composite

dietary measures) at 12 and 60 months.^{103,107,110,121,132} In five (n=3,506) of the six trials that reported physical activity outcomes, medium- to high-intensity counseling interventions improved selected physical activity outcomes (including steps per day, minutes per week of moderate to vigorous physical activity, percent meeting physical activity goal of 150 minutes per week, physical activity assessment score) at 6 and 12 months.^{103,110,121,123,132}

Two trials (n=2,594) reported only behavioral outcomes.^{109,114} One fair-quality trial, Logan Healthy Living (n=434), evaluated a medium-intensity telephone-only combined lifestyle counseling intervention and found statistically significant improvements in fat, saturated fat, fiber, and fruit/vegetable intake at up to 18 months. This trial, however, did not find a statistically significant improvement in physical activity behaviors.¹¹⁴ The other fair-quality trial, NERS (n=2,160), evaluated a medium-intensity physical activity–only counseling intervention and found an improvement in total physical activity (approximately 35 minutes more per week) at 12 months.¹⁰⁹

Ten trials evaluated medium- to high-intensity physical activity–only counseling interventions.^{98,99,104,109,122,123,128,130,131,141} Overall, while there was no consistent benefit observed for intermediate health outcomes, the limited number of trials and heterogeneity among these trials did not allow for any definitive conclusion of lack of benefit on intermediate outcomes for physical activity–only counseling interventions. Findings for behavioral outcomes in these trials are generally consistent with the findings for intermediate health outcomes (**Tables 21–24; Appendix G Table 2**). The two trials (n=125) that demonstrated a benefit on intermediate health outcomes showed an increase in self-reported physical activity outcomes.^{104,141} Trials that found no benefit on intermediate outcomes found no statistically significant benefit on self-reported physical activity outcomes (including total or leisure physical activity, percent meeting physical activity guidelines). Five of the 10 trials only reported short-term outcomes (<12 months).^{104,122,128,130,141} Three of these counseling trials (n=608) used objective measures of cardiorespiratory fitness and found no statistically significant benefit at 6 to 12 months.^{98,122,130} Self-reported measures of physical activity varied across trials—the most commonly reported measures included total energy expenditure, steps per day, minutes per week of total or moderate to vigorous physical activity, and percent meeting physical activity goal (150 minutes/week). Five (n=4,209) of 10 trials reported outcomes at 12 months or greater.^{98,99,109,123,131} Four (n=3,439) of these five trials found statistically significant improvements in self-reported physical activity outcomes at 12 to 24 months.^{98,99,109,123} One of these trials, NERS (n=2,160), only reported behavioral outcomes.¹⁰⁹ This trial was conducted in the United Kingdom and evaluated a medium-intensity physical activity–only counseling intervention that also offered access to low-cost exercise classes. This trial found an improvement in total physical activity (approximately 35 minutes more per week) at 12 months.

Four trials reported subgroup analyses for behavioral outcomes that allow for direct comparisons of findings between men and women, as well as older and middle-aged adults.^{107,109,123,145} While two of these trials (n=5,381) suggest that men had greater improvement in self-reported physical activity change at 12 months,^{107,123} two trials (n=2,401) found no difference by sex in physical activity outcomes at 12 or 36 months.^{109,145} Two trials (n=3,038) suggest no statistically significant differences in behavioral outcomes by age, such that older adults also appear to benefit from counseling aimed at improving physical activity levels.^{109,123}

KQ 4. What Are the Adverse Effects of Healthy Diet and/or Physical Activity Behavioral Counseling Interventions in Adults With Known CVD Risk Factors?

Overall Results

We narrowly focused this question on harms of counseling interventions, rather than broadly on harms of dietary or physical activity changes themselves. We examined the 74 trials included for KQs 1 through 3 for harms, as defined by the study authors, or any paradoxical change in outcomes (e.g., worsening of blood pressure, lipids, glucose, measures of weight, dietary intake, physical activity) (**Tables 1 and 2**). While we searched for additional studies examining harms of healthy lifestyle counseling interventions, we did not find any such studies.

Overall, the harms of included counseling interventions were very sparsely reported, although we did not a priori hypothesize that these counseling interventions would result in serious harms (i.e., unexpected or unwanted medical attention). Only 10 of the included trials explicitly mentioned harms or lack of harms (**Tables 1 and 2**). In general, the included interventions did not have significant adverse effects. While four trials reported increased complaints in persons receiving behavioral counseling attributed to an increase in physical activity,^{89,98,123,130} there were generally no serious injuries, except for one trial targeting older adults.⁹⁸ We found no consistent evidence for paradoxical changes in intermediate or behavioral outcomes. While nine of the 13 trials that reported carbohydrate intake reported an increase in carbohydrate intake, this increase was generally accompanied by dietary improvements in fat, saturated fat, fiber, and fruits and vegetables, without an overall increase in sugar or total calories consumed.^{71,75,80,89,96,118,138,146,147}

Detailed Results for Harms

Six fair- to good-quality trials (n=2,420) that evaluated medium- to high-intensity combined diet and physical activity counseling interventions specifically reported no adverse events during the trial.^{92,94,96,116,117,146} The mean age of participants in these trials ranged from 52 to 66 years. While four trials report “no adverse events,” they did not offer any additional details.^{92,94, 96,146} The PREMIER (n=304, hypertension subgroup only) trial was aimed at lowering blood pressure in persons (mean age, 52 years) who were not yet taking medications and reported no differences between intervention arms in serious adverse events, including cardiovascular or musculoskeletal events, at 6 months.¹¹⁶ TONE (n=975) was aimed at lowering blood pressure in persons (mean age, 66 years) who were already taking antihypertension medications; it reported no differences between intervention arms in “excessive” weight loss, physical injury, palpitations, chest pain, dizziness, edema, headaches, and “any” adverse events at 36 months.¹¹⁷

Six fair- to good-quality trials (n=3,961) that evaluated different medium- to high-intensity counseling interventions specifically reported adverse events during the trial.^{89,98,113,114,123,130} The Logan Healthy Living trial (n=434) was aimed at persons with hypertension or diabetes in Australia with a mean age of 58 years. This trial reported that three persons allocated to the intervention arm, a medium-intensity telephone-counseling intervention, died of unknown causes

during the 18-month trial.¹¹⁴ No additional details are reported. Another trial conducted by Rodriguez and colleagues (n=533) evaluated a medium-intensity combined lifestyle counseling intervention in persons with hypertension (mean age, 67 years). The authors reported that nine participants were withdrawn during the 12-month trial by research staff because of an adverse event that would affect study participation, but no additional details (including how many participants in each arm) are given.¹¹³ DPP (n=2,161), a high-intensity combined lifestyle counseling intervention aimed at preventing diabetes in overweight persons with impaired fasting glucose (mean age, 51 years), reported slightly more musculoskeletal complaints (i.e., myalgia, arthritis, arthralgia) in the intervention group receiving a high-intensity counseling intervention at 2.8 years (24.1 vs. 21.1 events per 100 person-years in the intervention and control groups, respectively; $p < 0.02$).⁸⁹ Gastrointestinal symptoms (diarrhea, flatulence, nausea, vomiting) were more common in the control group. The trial reported no differences in hospitalizations between the intervention arms. Three trials evaluating physical activity–only counseling interventions reported complaints due to increased exercise.^{98,123,130} The Lifestyle Intervention and Independence for Elders trial (n=186) was aimed at older adults with a mean age of 67 years. This trial reported that one participant in the high-intensity counseling group withdrew because of fatigue attributed to exercise at 11 months.¹³⁰ The Enhanced Fitness Trial (n=302), which was also aimed at older adults at the VA with a mean age of 67 years, reported a total of 691 adverse events during the 12-month trial, 650 (94%) of which were classified as nonserious (e.g., aches, pain, sore muscles, headaches, minor injuries).⁹⁸ Of the 64 (6%) events classified as serious (life threatening or requiring hospitalization), two events were attributed to physical activity. Both of these events occurred in the intervention group receiving a high-intensity counseling intervention—one person had angina while on a treadmill requiring hospitalization and the other person fell from the treadmill and broke his femur. A third physical activity counseling trial (n=878), the Green Prescription Programme, with a mean age of 58 years, reported increased “bodily pain” at 12 months ($p = 0.02$) as measured by the SF-36 in the medium-intensity counseling intervention group compared with the wait list control group.¹²³ The authors stated, however, that there was no difference between the trial arms in falls, injuries, or hospital admissions at 12 months.

In examining the included trials, we found no consistent evidence that behavioral counseling resulted in unwanted paradoxical effects in intermediate or behavioral outcomes. Two fair-quality trials with a number of methodological limitations had paradoxical findings in intermediate health outcomes.^{83,92} One small trial (n=92) conducted in Sweden in participants with a mean age of 42 years found lower HDL cholesterol at 12 months in the intervention group receiving a medium-intensity dietary counseling intervention compared with the usual care control group.⁸³ The authors note, however, that more women were included in the control group (accounting for higher HDL cholesterol in the control group) and results were not adjusted for sex differences. Another trial (n=307), Healthy Living Course, aimed at persons with impaired fasting glucose, reported a greater incidence of diabetes in the high-intensity counseling intervention group (n=24) than the control group (n=7) at 6 months ($p = \text{not reported}$).⁹² We found no evidence that medium- or high-intensity counseling interventions negatively affected dietary intake or physical activity. Thirteen trials reported carbohydrate intake as a self-reported dietary outcome.^{70,71,75,89,91,94,118,119, 138,146-149} Four trials (n=654) reported no change in carbohydrate intake,^{70,90,94,119} while nine (n=4,387) of the 13 trials reported an increase in consumption of carbohydrates in the intervention group compared with the control group at 6 to 36 months.^{71,75,}

80,89,96,118,138,146,147 The increased consumption of carbohydrates was generally accompanied by corresponding dietary improvements in decreased consumption of fat and saturated fats and increased consumption of fiber and fruits and vegetables. None of these trials reported an overall increase in total calories consumed. In fact, most often an increased consumption of carbohydrates was accompanied by a decrease in total calories consumed. Therefore, we did not consider the increase in carbohydrate consumption in the intervention group to represent a harm. In ADAPT (n=241), the authors suggest that a decrease in high-fat dairy products in the intervention group that was not replaced with low-fat dairy products could potentially result in a decrease in calcium consumption.¹³⁸

Chapter 4. Discussion

Summary of Evidence

We conducted this systematic review to assist the USPSTF in updating its previous recommendations on physical activity and healthy diet counseling.^{55,150,151} This review focused on the effectiveness and harms of primary care–relevant diet and physical activity counseling interventions in persons with CVD risk factors. We included 74 unique trials that met our inclusion criteria, the vast majority of which (k=51) were published since the previous USPSTF recommendations in 2002.

Based on a large body of evidence (k=71), we found that intensive combined lifestyle counseling in persons with CVD risk factors reduced cholesterol, blood pressure, measures of weight, glucose, and diabetes incidence at 12 to 24 months (**Table 25**). Effects of counseling interventions (k=61) on objectively measured or self-reported behavioral outcomes were generally consistent with findings on intermediate health outcomes. We found more limited information about longer-term benefits. Benefits on blood pressure, measures of weight, and glucose reduction appear to persist after 24 months, but are based on only a small subset of trials with longer-term followup. Reduction in diabetes incidence appears to persist for 3 to 4 years. Several trials evaluated a diet-only counseling message. Intensive diet-only counseling in persons with dyslipidemia also reduced cholesterol. Both medium- and high-intensity interventions reduced lipids, blood pressure, and measures of weight. High-intensity interventions reduced glucose and diabetes incidence. In general, effective counseling interventions were intensive and involved several hours (median, 13 hours [IQR, 9 to 19 hours]), over several contacts (median, 8 contacts [IQR, 5 to 16 contacts]), over several months duration (median, 12 months [IQR, 6 to 12 months]). We found more limited information about physical activity–only counseling interventions. Mostly medium-intensity physical activity–only counseling in persons with CVD risk factors did not appear to have consistent benefits on intermediate health outcomes, but trials were quite heterogeneous in populations studied, interventions evaluated, and outcomes measured. While findings were mixed for physical activity–only counseling interventions, the limited number of studies and heterogeneity across trials limits our ability to make any definitive conclusions about the benefits, or lack thereof, of these types of counseling interventions. Four of the five physical activity–only counseling trials that reported outcomes at 12 to 24 months, however, found statistically significant improvements in self-reported measures of physical activity.^{98,99,109,123}

Only a small subset of trials (k=16) reported patient health outcomes, which prevented us from drawing any definitive conclusions as to whether these types of interventions can decrease CVD events or improve QOL.^{85,86,89,92,94,95,98,110,115-122} Overall, there does not appear to be a significant reduction in CVD events in the long term, but event rates in these trials, even after 10 years of followup, are generally quite low. Findings of benefit on self-reported QOL measures were mixed. Likewise, only a small subset of trials (k=10) reported on harms of counseling interventions, but overall we found no serious harms, with the exception of two adverse events in one physical activity counseling intervention aimed at older adults.^{89,94,98,113,114,116,117,123,130,138,146}

There are surprisingly few current existing systematic reviews addressing the effectiveness or harms of lifestyle behavioral counseling in persons with traditional CVD risk factors. Most recent reviews of lifestyle counseling interventions focus on obesity management or CVD prevention in populations with known diabetes and/or coronary heart disease. Our review found a similar reduction in progression to diabetes as in existing systematic reviews examining the effectiveness of these types of interventions to prevent diabetes in persons with impaired fasting glucose or glucose intolerance.¹⁵²⁻¹⁵⁵ Our review found a similar reduction in blood pressure and cholesterol as a Cochrane review of multiple risk factor interventions for the primary prevention of CVD by Ebrahim and colleagues.¹⁵⁶ The Cochrane review, however, also found a decrease in mortality, primarily due to the inclusion of trials of early CVD prevention. Given the applicability of many earlier trials to current understanding and management of CVD risk, as well as trends in the distribution of CVD and its risk factors over time, our review was restricted to trials published after 1990.

Clinical Interpretation of Benefit and Harms Given Paucity of Direct Health Outcome Data

Effects on Lipids and Blood Pressure

Medium- to high-intensity combined lifestyle or diet-only counseling interventions decreased total cholesterol by approximately 3 to 8 mg/dL and decreased LDL cholesterol by approximately 1.5 to 6 mg/dL at 12 to 24 months. Based on observational data, a 10 percent reduction (approximately 20 mg/dL) in total cholesterol is associated with a decreased incidence of CAD by approximately 54 percent at age 40 years, 39 percent at age 50 years, and 27 percent at age 60 years.¹⁵⁷ Although plausible, it is still unclear if smaller reductions in cholesterol can also translate into reductions in CAD or CVD events.

Medium- to high-intensity combined lifestyle interventions can decrease SBP and DBP by approximately 1 to 3 and 1 to 2 mm Hg, respectively, at 12 to 24 months. Long-term observational followup of Trials of Hypertension Prevention I and II (n=3,126) showed that persons with prehypertension who were initially randomized to receive intensive lifestyle counseling had decreased composite CVD events over 10 to 15 years (HR, 0.70 [95% CI, 0.53 to 0.94]), suggesting that small reductions in blood pressure (i.e., approximately 2 mm Hg reduction in SBP and 1 mm Hg reduction in DBP) seen in the original Trials of Hypertension Prevention may result in longer-term reduction in CVD morbidity and mortality.¹⁵⁸ Epidemiologic data also suggest that small changes in blood pressure (i.e., 2 mm Hg reduction in SBP) are associated with a decreased risk for CAD by 6 percent or cerebrovascular accident by 16 percent.¹⁵⁹

Effects on Glucose and Diabetes Incidence

Medium- to high-intensity combined lifestyle counseling interventions decreased fasting glucose and diabetes incidence. The reduction in fasting glucose across all 18 trials reporting this outcome was approximately 0.5 to 3.5 mg/dL at 12 to 24 months. Fewer trials (k=8) reported

diabetes incidence at 12 to 24 months; these trials were generally high-intensity combined lifestyle counseling interventions aimed at persons with impaired fasting glucose or glucose tolerance. In the long term (>24 months), the overall pooled estimate of RR for high-intensity combined lifestyle counseling was 0.61 (95% CI, 0.46 to 0.79). In DPP, for example, fasting blood glucose was approximately 4 mg/dL lower in the intensive lifestyle counseling group than the control group at 3 years, which corresponded to 14.4 percent of persons developing diabetes in the intervention group compared with 28.9 percent in the control group (number needed to treat [NNT], about 7 [95% CI, 5 to 10]). The lifestyle intervention was more effective than metformin alone in reducing diabetes incidence (results were 39% lower [95% CI, 24 to 51]). Even in populations with lower rates of progression to diabetes than DPP, one would not have to intensively counsel many individuals to prevent a single case of diabetes mellitus. If only 10 percent of persons in the control group progress to diabetes over 3 to 6 years, for example, then the NNT would be 26 (95% CI, 19 to 48); if 20 percent of persons progress to diabetes, then the NNT would be 13 (95% CI, 9 to 24); if 25 percent of persons progress to diabetes, then the NNT would be 10 (95% CI, 7 to 19); and if 33 percent of persons progress to diabetes, then the NNT would be 8 (95% CI, 6 to 14).

Effects on Weight Outcomes

Medium- to high-intensity combined lifestyle counseling interventions also decreased weight outcomes by a standardized effect size of 0.24 (95% CI, 0.35 to 0.14) at 12 to 24 months. The statistical heterogeneity for this pooled effect was very high, however, and therefore should be interpreted with caution. Overall, this represents a small effect in weight reduction. When this effect size is back translated into individual trials, the effect is approximately equivalent to a 2- to 3-kg weight loss or 0.5- to 1.5-kg/m² decrease in BMI. These results are generally consistent with the small effects found in a recent systematic review of behavioral treatment of adult obesity. This review found that behavioral treatment resulted in an average of 3 kg of weight loss in the intervention versus control groups.⁵⁷ Our findings are also consistent with the 2013 AHA/ACC/Obesity Society Guideline for the Management of Overweight and Obesity in Adults, which found strong evidence to support the association of sustained weight loss of 3 to 5 percent and clinically meaningful reductions in triglycerides and glucose outcomes.¹⁶⁰ Epidemiological data also suggest that the risk for both CVD and diabetes increases with each kg/m² unit change in BMI.¹⁶¹ However, it is still unclear if small sustained reductions in weight or BMI after the intervention's conclusion translate into better cardiovascular patient health outcomes (i.e., decreased CVD events and/or mortality from CVD or diabetes). The clinical significance of changes in weight measures should therefore primarily be based on accompanying changes in lipid, blood pressure, and glucose outcomes.

Effects on Increases in Self-Reported Physical Activity

Medium-intensity physical activity–only counseling trials generally found no effect on intermediate health outcomes at 12 to 24 months. Four of the five counseling trials that reported behavioral outcomes at 12 to 24 months found statistically significant improvements in physical activity in the intervention versus control groups.^{98,99,109,123} These trials used different measures of physical activity and found a 10 to 25 percent increase in the percentage of persons who met

the recommended 150 minutes per week of moderate-intensity exercise ($k=2$)^{98,123} and an approximate 35-minute/week increase in moderate or total physical activity ($k=2$).^{99,109} This increase in the amount of physical activity per week is similar to findings in our previous review in adults without cardiovascular risk factors.⁵⁵ It is clear that increased physical activity is associated with a decrease in CVD events and mortality.¹⁶² Based on a meta-analysis by Stattelmair and colleagues of 33 observational studies to determine the dose-response between levels of physical activity and risk for CAD, it appears that persons who had 150 minutes per week of physical activity had a 14 percent lower CAD risk. Persons who were physically active at levels lower than recommended also had statistically significant lower risk.¹⁶³ This finding supports the 2008 Physical Activity Guidelines for Americans and the American College of Sports Medicine recommendations for 150 minutes per week of moderate-intensity exercise, with the caveat that adults who are unable or unwilling to meet this goal still benefit from engaging in amounts of exercise less than recommended.^{162,164} Another review by Zheng and colleagues of 12 studies to quantify the dose-response between walking and CVD risk found that an increase of approximately 30 minutes per week was associated with a 19 percent lower CAD risk.¹⁶⁵ Based on extrapolation from observational studies, it is likely that even a modest increase in the percentage of persons meeting a recommended 150 minutes per week of moderate-intensity activity or a modest increase in total or moderate-intensity activity per week can lower incidence of CAD and CAD events.

Adverse Effects

We did not a priori hypothesize any serious harms for counseling intervention. Overall, a limited number of trials reported on adverse effects of interventions and only one trial in older adults found two events of serious harms resulting from physical activity.⁹⁸ Observational studies from our previous systematic review of lifestyle counseling interventions suggest an increased risk for serious cardiac events during vigorous physical activity, primarily in persons with low levels of habitual activity.⁵⁵ The absolute risk for serious cardiac events related to physical activity, however, appears to be extremely small. In these observational studies, minor musculoskeletal injuries were fairly common when participants increased their physical activity from their habitual levels. The type and total amount of activity and relative change in activity were all important factors in determining the risk for injury. Noncontact, low-impact activities had lower injury rates, including walking, bicycling, and swimming. Increasing physical activity in a series of small increments, each followed by an adaptation period, resulted in lower rates of injury.¹⁶⁶ Additional information regarding harms of physical activity are detailed in the DHHS 2008 report on physical activity.¹⁶⁶ Therefore, focusing on low-impact activities and increasing activity in small increments can mitigate serious harm or injury from counseling interventions in older adults or persons at high risk for injury.

Considerations for Applicability of Findings

Population Considerations

Our review's findings are widely applicable to a broad range of individuals with CVD risk factors, including dyslipidemia, hypertension, impaired fasting glucose, glucose intolerance,

metabolic syndrome, obesity, and smoking. Our review did not include trials conducted exclusively in persons with diabetes or in populations selected exclusively for obesity. Nearly all trials included persons who were overweight or obese. Several trials also included some persons who were already diagnosed with diabetes. Included trials also involved persons who had not yet started antihypertension or lipid-lowering medications, as well as those already taking them. Although included trials provided little direct evidence of comparisons of findings between the two sexes and across different age or racial/ethnic groups, we have no reason to believe that the benefit of intensive counseling would not apply to both men and women, middle-aged and older adults, and nonwhite subpopulations (namely African and Latino Americans), given the fair representation of these groups across included trials. Serious harms from increased physical activity were reported in one trial in older adults. As such, older adults may be at increased risk for adverse events, but very sparse reporting of harms limits any definitive conclusions about harms, much less differential harms between subpopulations.

Trials varied in their recruitment strategies, the restrictiveness of the eligibility criteria, and recruitment and retention rates. Of the trials with adequate reporting about recruitment methods, 16 trials relied on volunteers as part ($k=8$) or all ($k=8$) of their recruitment strategy. Most trials had eligibility criteria excluding persons with acute medical conditions or any known serious medical conditions. The proportion of trial participants out of the entire eligible sample ranged from 15 to 100 percent ($k=53$). The majority of trials had very high recruitment rates, with only 10 trials having less than 50 percent of eligible participants randomized into the trial. Overall, retention rates in the trials were greater than 80 percent. Sixteen trials had retention rates less than 80 percent. Trials with volunteer participants, restrictive eligibility criteria, low recruitment rates, and/or high retention rates likely overestimate the true magnitude of benefit of these counseling interventions in real-world settings.

Intervention Considerations

Effective interventions were medium- to high-intensity combined lifestyle or diet-only counseling interventions. Medium-intensity interventions are defined as greater than 30 minutes up to 360 minutes of contact. Approximately two thirds of the medium-intensity interventions had 120 minutes of contact time or greater; the median number of contacts was five and median duration of the intervention was 9 months. Diet-only and physical activity-only counseling interventions were mostly medium-intensity. High-intensity interventions had greater than 360 minutes of contact; the median number of contacts was 16 and median duration of the intervention was 12 months. Specially trained individuals delivered these interventions, including dietitians or nutritionists, physiotherapists or exercise professionals, as well as health educators, nurses, or psychologists.

Counseling interventions generally focused on behavioral change and could include cointerventions. Ten trials explicitly reported medication adjustment or counseling on medication adherence as part of the intervention protocol. In one of these 10 trials, the intervention protocol for medication adjustment focused on withdrawal or tapering off of antihypertension medications.¹¹⁷ Several trials explicitly stated provision of free or low-cost access to exercise classes (although supervised exercise was not mandatory). Only two trials

reported provision of financial incentives for participation, and two other trials offered some provision of free food to intervention participants (but were not considered to be feeding trials). Adherence, and therefore effectiveness, in trials may be higher than in real-world practice, especially for higher-intensity interventions. Unfortunately, measures of adherence and fidelity were not consistently reported in included trials. Thirty-three of the 74 trials reported adherence.^{72-74,76,77,80-82,84,86,87,89,90,92,94,98,99,105,107,114,116,118,122,127,129,130,132-134,137,146,167,168} Adherence in the 13 trials that reported the proportion of participants who attended all of the sessions ranged from 50 to 95 percent.^{74,77,81,84,87,91,116,122,127,129,130,137,167} Adherence in the seven trials that reported the proportion of participants who received any intervention ranged from 46 to 99 percent.^{72,82,86,99,105,133,134}

Based on included trials, we are not able to define the minimum necessary counseling components for an effective intervention. All included counseling interventions involved more than didactic education alone. Most of these trials included audit and feedback (including self-monitoring), problem solving skills, and individualized care plans. Using qualitative analyses and meta-regressions, we did not find that the intervention format (e.g., face-to-face, group, individual, phone), the person delivering the counseling, the number of sessions, or the duration of intervention significantly affected the direction or magnitude of benefit. Based on a meta-analysis by Michie and colleagues of combined lifestyle counseling interventions specifically using meta-regressions to examine a number of a priori-specified intervention components, it appears that interventions with “self-monitoring” and use of at least one “self-regulatory technique” derived from control theory (i.e., prompt intention formation, prompt specific goal setting, provide feedback on performance, prompt self-monitoring behavior, prompt review of behavioral goals) were significantly more effective than interventions not including these components.¹⁶⁹ This review found that the duration of the intervention, the person delivering the counseling, the intervention format (i.e., individual vs. group), the study setting, the number of included sessions, or the number of behavior change techniques employed did not distinguish between effective and ineffective interventions. Greaves and colleagues conducted a systematic review of existing reviews of diabetes prevention lifestyle counseling and found that interventions that targeted both diet and physical activity, mobilized social support, used well-established behavior change techniques, used self-regulatory techniques (i.e., goal setting, self-monitoring, feedback on performance, and goal review), and had greater contact time or frequency of contact had greater effectiveness.¹⁷⁰ The review by Greaves and colleagues did not identify a minimum threshold of time/intensity that was effective and did not find any clear associations between intervention effectiveness and the person delivering counseling, the study setting, or the intervention format.

Review Limitations

Eating a healthy diet and increasing physical activity clearly have health benefits beyond CVD prevention and CVD risk factor modification. To support the USPSTF recommendation process, however, our review focused narrowly on the primary prevention of CVD in persons with risk factors for CVD. Therefore, we excluded persons with known diabetes, coronary heart disease, cerebrovascular disease, peripheral artery disease, and chronic kidney disease. We previously conducted a similar review of behavioral counseling interventions for the primary prevention of

CVD focused on unselected populations and persons without known risk factors, as well as a review on the management of adult obesity, which included behavioral interventions.^{55,57} Therefore, this systematic review represents only a subset of a much larger body of literature on diet and physical activity counseling interventions in other populations and similar interventions with different specific aims (i.e., to prevent other diseases [e.g., cancer] or conditions [e.g., falls/disability]). Our review also focused on interventions that were relevant to primary care (i.e., those that could be conducted in or referred from primary care). Therefore, our review excluded behavioral interventions delivered through worksites, schools, and community organizations (e.g., churches); for these, we refer the reader to the CDC's Community Preventive Services Task Force.¹⁷¹ Additionally, we limited included studies of effectiveness to fair- to good-quality randomized, controlled trials or controlled clinical trials conducted in developed countries so as to identify the evidence with the least risk for bias and the highest applicability to current U.S. practice. We only included studies published after 1990. We also excluded trials without a true control arm (e.g., usual care, minimal intervention, attention control, wait list control). As a result, we did not address literature addressing the comparative effectiveness of different types of behavioral counseling and intervention elements.

We categorized and pooled clinically heterogeneous interventions and lengths of followup in order to synthesize the evidence. We categorized length of followup into short (<12 months), intermediate (12 to 24 months), and long (>24 months). We pooled outcomes according to these categorizations. Likewise, we categorized interventions by intensity (minutes of persons-contact) rather than total number of, or duration of contacts. While this categorization scheme is consistent with the definitions of intensity used in our previous work supporting the USPSTF healthy lifestyle counseling recommendation, it is somewhat arbitrary, and some "medium-intensity" interventions were still quite intensive (in terms of minutes, frequency, and duration of contacts). Furthermore, because of limitations in reporting of intervention characteristics in the published literature, we had to estimate the duration of contacts in several instances. Our assumptions in these instances, however, would not change the overall categorization of intensity (low, medium, high). Therefore, we use gross categorizations of "intensity" rather than report actual minutes of contact.

There were also limitations posed by the quantitative pooling of results. Of the 71 trials, only 14 trials could not be included in meta-analyses because of limitations in reporting at the primary study level (e.g., no measure of dispersion). Of the data included in the meta-analyses, some degree of calculation was necessary to include the trials in the meta-analyses, although only a small percentage required statistical judgment. These calculations included determining that an abnormally small value reported as a standard deviation was actually a standard error and estimating the correlation between baseline and followup values in order to calculate the standard deviation of the change score. In these instances, we erred on the side of avoiding a type I error or overestimation of effect size.

We purposefully pooled across a clinically heterogeneous body of counseling literature. For most outcomes, the statistical heterogeneity was moderate and, therefore, was still reasonable to allow for the interpretation of pooled estimates. Given the clinical heterogeneity and our use of random-effects analyses, confidence interval estimates should be primarily used to understand the magnitude of effects on the individual outcomes. There was considerable statistical

heterogeneity for fasting blood glucose and weight outcomes. As a result, one should interpret pooled estimates with caution. Likewise, we believe the clinical significance of the overall reduction in weight across trials should be interpreted in the context of the accompanying reductions in lipids, blood pressure, and measures of glucose. Despite examining for a number of factors that may explain for the heterogeneity of findings across trials, we were unable to identify additional population, intervention, or study characteristics that explained the statistical heterogeneity in pooled analyses (other than at a gross level of population targeted and intervention type).

Other potential sources of risk for bias in our review includes limiting the search to English-only publications, only including published trials, potential selective reporting of outcomes, and including trials that used volunteer participants. Egger's statistical test for small-study effects was significant only for triglyceride outcomes, which we do not discuss at length.

Study Limitations and Future Research Needs

Behavioral counseling to prevent CVD is a very active field of research and numerous trials in persons at risk for CVD are currently underway (**Appendix B**). Despite a very large body of trial evidence, well-conducted trials (and funding for these trials) are still needed to understand the full impact of these behavioral interventions on important health outcomes. Additional studies should also determine if less-intensive interventions are as effective as higher-intensity counseling.

While medium- to high-intensity combined lifestyle and diet-only interventions are effective, many of the high-intensity interventions would require resources that are not currently available or paid for in the current health system (and real-world patient adherence to intensive counseling may be considerably lower than in included trials). Additional research on how best to disseminate and implement these types of intensive behavioral counseling interventions into current practice is needed. Details on the fidelity of and adherence to counseling interventions should be routinely reported to better understand the applicability of behavioral counseling trial findings. We found a wide range of intensity for effective interventions, from a couple hours to greater than 30 hours of contact time. Future research should also evaluate if lower-intensity counseling interventions (e.g., a couple hours) are as effective as higher-intensity counseling (e.g., DPP) or if there is a minimum intensity, frequency, or duration of contact that could still improve lipids, blood pressure, and diabetes incidence. Evaluating true low-intensity interventions may not be feasible given that the standard of care for persons with CVD risk factors is at least minimal counseling. Future research on different modalities that require minimal health care resources (i.e., technology-based counseling), and therefore “lower the intensity” of interventions, is advisable.

It is clear that healthy diet and physical activity behaviors both contribute to good cardiovascular and overall health. Additional research on the additive or differential benefit of different counseling messages (i.e., diet, physical activity, or both) in different populations would be helpful in determining whether clinical scenarios focusing on diet or physical activity alone is advisable (or preferable) to combined lifestyle counseling.

Only a limited number of trials (k=11) reported followup beyond 24 months.^{69,89,91,93,107,115,117,118,138,139,149} While it is clear that high-intensity counseling interventions can reduce diabetes incidence in the long term, additional trials are needed to determine if beneficial effects of reductions in other important intermediate health outcomes are reproducible in the longer term. Many of the trials that had longer-term followup were high-intensity interventions with ongoing maintenance sessions throughout the trial period. Therefore, relatively little is known about the maintenance of beneficial physiologic (or behavior) change after an active intervention ends. Trials evaluating lower-intensity interventions rarely report longer-term outcomes. If additional evidence supports the effectiveness of low- to medium-intensity interventions, longer-term followup for these interventions would also help us understand the benefits of these interventions.

Given the progress of medical care and other factors, CVD events are relatively low. Therefore, the sample sizes and length of followup for counseling trials are likely to be prohibitively large or long if powered to detect differences in CVD outcomes. For example, the Look AHEAD (Action for Health in Diabetes) trial (n=5,145) that evaluated a high-intensity lifestyle intervention in overweight or obese persons with diabetes found no reduction in the rate of CVD events at about 10 years despite reductions in intermediate health outcomes (i.e., weight, glucose) and improvements in physical activity levels.¹⁷² Self-reported patient outcomes, namely health-related QOL measures, are in fact health outcomes (i.e., can be experienced by the patient) and are underutilized in this body of literature. Future research would benefit from measuring and consistently reporting QOL and related self-reported patient outcomes.

Given the mixed findings for physical activity–only counseling trials, future research replicating successful physical activity–only counseling interventions would help us determine if such types of counseling interventions work and the populations these interventions should target. Physical activity–only counseling trials were generally of lower intensity than other included trials. Future research on the effectiveness of higher-intensity counseling interventions, especially in persons with CVD risk factors, is advisable. We primarily found evidence of increases in self-reported measures of physical activity. Greater use of objective measures to assess physical activity (i.e., step counts using pedometers, VO_2max to measure cardiorespiratory fitness) would corroborate self-reported changes in physical activity level, which is especially important when the changes in magnitude are small.

Conclusions

In general, medium- to high-intensity diet and physical activity behavioral counseling in persons with CVD risk factors resulted in consistent improvements across a variety of important cardiovascular intermediate health outcomes, including total and LDL cholesterol, blood pressure, glucose, and weight outcomes up to 2 years. Overall, high-intensity combined lifestyle counseling can reduce diabetes incidence at 3 to 4 years. The applicability of intensive counseling interventions depends largely on their availability and real-world adherence to these interventions. Very limited evidence exists on health outcomes or harmful effects of these counseling interventions. Extrapolating from other bodies of literature, the improvements we observed in intermediate health outcomes could translate into long-term reduction in CVD

events. It is unlikely that intensive counseling interventions have serious patient harms. Future research on behavioral counseling in this population should focus on the effectiveness of lower-intensity interventions and should consistently include self-reported measures of health-related QOL.

Figure 1. Analytic Framework: Behavioral Counseling to Promote a Healthy Lifestyle for Cardiovascular Disease Prevention in Persons With Cardiovascular Risk Factors

Abbreviations: CVD = cardiovascular disease; BMI = body mass index.

Figure 2. Pooled Analysis of Total Cholesterol in Persons With Dyslipidemia, Sorted by Length of Followup Time

Population with Dyslipidemia
Outcome=Total Cholesterol (mg/dL)

Figure 3. Pooled Analysis of Low-Density Lipoprotein Cholesterol in Persons With Dyslipidemia, Sorted by Length of Followup Time

**Population with Dyslipidemia
Outcome=LDL (mg/dL)**

Figure 4. Pooled Analysis of Total Cholesterol in Persons With Dyslipidemia or Multiple Risk Factors, Sorted by Length of Followup Time

**Population with Dyslipidemia or Multiple Risk Factors
Outcome=Total Cholesterol (mg/dL)**

Figure 5. Pooled Analysis of Low-Density Lipoprotein Cholesterol in Persons With Dyslipidemia or Multiple Risk Factors, Sorted by Length of Followup Time

Population with Dyslipidemia or Multiple Risk Factors
Outcome=LDL (mg/dL)

Figure 6. Pooled Analysis of Weight in Persons With Dyslipidemia or Multiple Risk Factors, Sorted by Length of Followup Time

**Population with Dyslipidemia or Multiple Risk Factors
Outcome=Adiposity**

Figure 7. Pooled Analysis of Systolic Blood Pressure in Persons With Hypertension, Sorted by Length of Followup Time

Population with Hypertension
Outcome=Systolic Blood Pressure (mm Hg)

Figure 8. Pooled Analysis of Diastolic Blood Pressure in Persons With Hypertension, Sorted by Length of Followup Time

Population with Hypertension
Outcome=Diastolic Blood Pressure (mm Hg)

Figure 9. Pooled Analysis of Systolic Blood Pressure in Persons With Hypertension or Multiple Risk Factors, Sorted by Length of Followup Time

Population with Hypertension or Multiple Risk Factors
Outcome=Systolic Blood Pressure (mm Hg)

Figure 10. Pooled Analysis of Diastolic Blood Pressure in Persons With Hypertension or Multiple Risk Factors, Sorted by Length of Followup Time

**Population with Hypertension or Multiple Risk Factors
Outcome=Diastolic Blood Pressure (mm Hg)**

Figure 11. Pooled Analysis of Weight in Persons With Hypertension or Multiple Risk Factors, Sorted by Length of Followup Time

Population with Hypertension or Multiple Risk Factors
Outcome=Adiposity

Figure 12. Pooled Analysis of Diabetes Incidence in Persons With Impaired Fasting Glucose or Impaired Glucose Tolerance, Sorted by Length of Followup Time

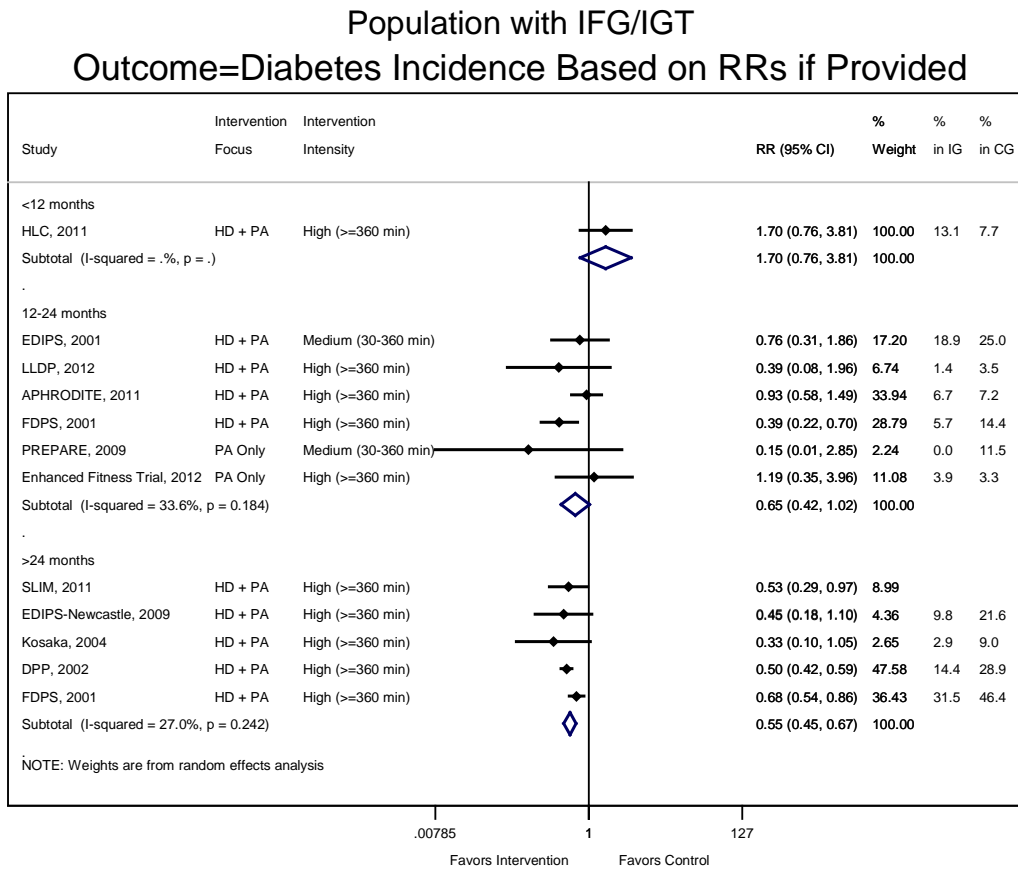

Figure 13. Pooled Analysis of Diabetes Incidence in Persons With Impaired Fasting Glucose, Impaired Glucose Tolerance, or Multiple Risk Factors, Sorted by Length of Followup Time

Population with IFG/IGT or Multiple Risk Factors
Outcome=Diabetes Incidence Based on RRs if Provided

Figure 14. Pooled Analysis of Fasting Glucose in Persons With Impaired Fasting Glucose or Impaired Glucose Tolerance, Sorted by Length of Followup Time

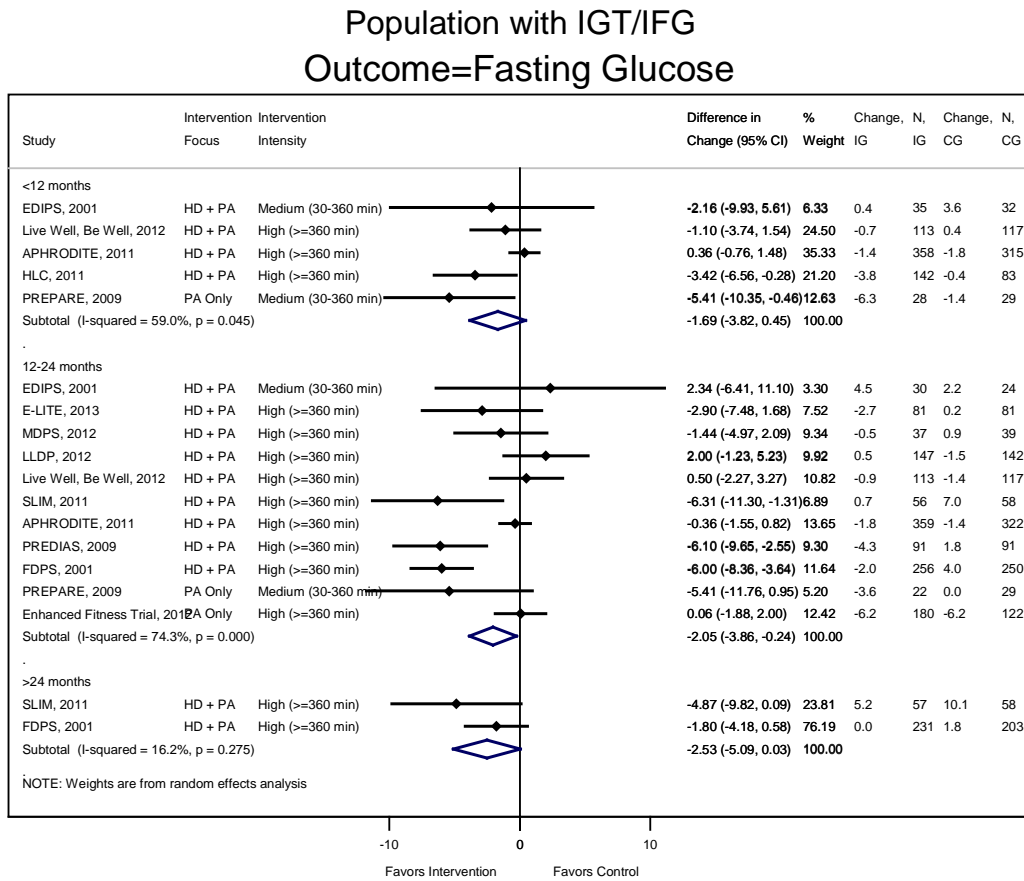

Figure 15. Pooled Analysis of Weight in Persons With Impaired Fasting Glucose, Impaired Glucose Tolerance, or Multiple Risk Factors, Sorted by Length of Followup Time

Population with IFG/IGT or Multiple Risk Factors
Outcome=Adiposity

Figure 16. Pooled Analysis of Total Cholesterol for Combined Healthy Diet and Physical Activity Interventions in All Risk Groups, Sorted by Length of Followup Time

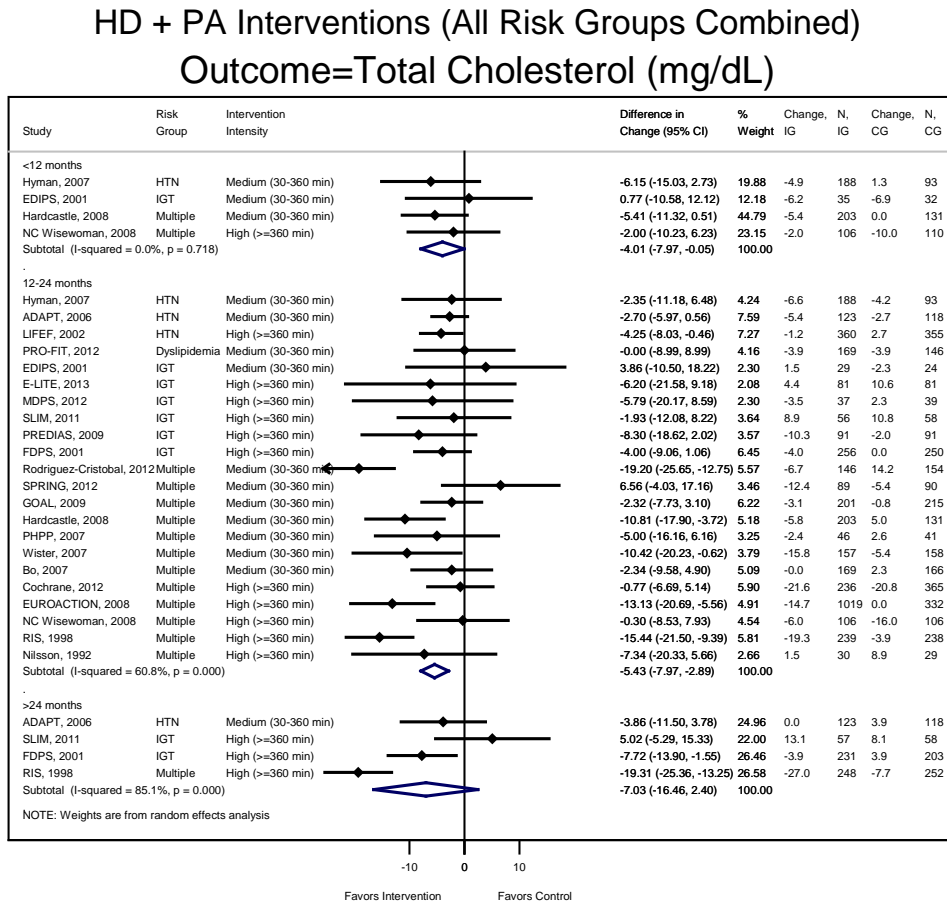

Figure 17. Pooled Analysis of Low-Density Lipoprotein Cholesterol for Combined Healthy Diet and Physical Activity Interventions in All Risk Groups, Sorted by Length of Followup Time

**HD + PA Interventions (All Risk Groups Combined)
Outcome=LDL (mg/dL)**

Figure 18. Pooled Analysis of Systolic Blood Pressure for Combined Healthy Diet and Physical Activity Interventions in All Risk Groups, Sorted by Length of Followup Time

**HD + PA Interventions (All Risk Groups Combined)
Outcome=Systolic Blood Pressure (mm Hg)**

Figure 19. Pooled Analysis of Diastolic Blood Pressure for Combined Healthy Diet and Physical Activity Interventions in All Risk Groups, Sorted by Length of Followup Time

**HD + PA Interventions (All Risk Groups Combined)
Outcome=Diastolic Blood Pressure (mm Hg)**

Figure 20. Pooled Analysis of Fasting Glucose for Combined Healthy Diet and Physical Activity Interventions in All Risk Groups, Sorted by Length of Followup Time

**HD + PA Interventions (All Risk Groups Combined)
Outcome=Fasting Glucose (mg/dL)**

Figure 21. Pooled Analysis of Diabetes Incidence for Combined Healthy Diet and Physical Activity Interventions in All Risk Groups, Sorted by Length of Followup Time

* Using 10-year FRS.

† Results are for IG1 and IG2 combined.

‡ Outcomes for 12 and 24 months unless otherwise noted.

§ Significant at 12 months, not at 24 months.

|| Outcomes derived from figure only.

¶ Among participants with HTN, those with HTN at followup.

Patients with metabolic syndrome only.

** Health outcomes for entire study population, not stratified by HTN status.

†† IG1 and IG2 combined; outcomes for subgroup with HTN unless otherwise noted.

‡‡ Among participants with HTN, percent with normal BP and no medications at 18 months.

§§ Outcomes for IG2 (weight loss) and IG3 (sodium + weight loss) unless otherwise noted.

||| Reports mean arterial pressure only.

¶¶ Significant at 24 months, not significant at 12 months.

Because of the adjustment of some reported data, values may be different than the unadjusted values reported in the meta-analysis.

*** Significant for IG2 only (BP reduction not significant for IG1 at 24 months).

Abbreviations: ADAPT = Activity Diet and Blood Pressure Trial; BMI = body mass index; CVD = cardiovascular disease; DBP = diastolic blood pressure; FBG = fasting blood glucose; HD = healthy diet; HDL = high-density lipoprotein; HIP = Health Improvement Project; HTN = hypertension; HTTP = Hypertension Teaching and Treatment Programme; LDL = low-density lipoprotein; LIHEF = Lifestyle Intervention against Hypertension in Eastern Finland; MD = physician; meds = medications; N = study population; NA = not available; NR = not reported; PA = physical activity; pt = patient; SBP = systolic blood pressure; TC = total cholesterol; TG = triglycerides; TONE = Trial of Non-Pharmacological Interventions in the Elderly.

Table 25. Overall Summary of Evidence by Key Question

Trials (k), Participants (n)	Overall quality	Consistency	Applicability	Summary of findings
<i>Key Question 1. Health outcomes</i>				
k=16 n=7,053	Fair: sparse reporting of health outcomes or use of clinically important self-reported health outcomes (i.e., QOL); generally low CVD event rates; variation in QOL instruments used	Generally consistent findings of no benefit on reduction of CVD events, mixed findings for benefit on QOL	Persons with any number of CVD risk factors, no major limitations in populations studied; mainly high-intensity combined lifestyle counseling interventions	Generally no reduction in CVD events (including mortality) at 6 to 79 months and at 10 years (k=4); no reduction in depression symptoms at 6 to 12 months (k=4); mixed findings on self-reported measures of QOL at 6 to 12 months (k=7). One earlier trial found a reduction in CVD events at 6.6 years (RR, 0.71 [95% CI, 0.51 to 0.99]) using a high-intensity intervention including a protocol to initiate medication in Swedish men at high risk for CVD (including 29% smokers, 22% with diabetes).
<i>Key Question 2. Intermediate outcomes</i>				
k=71 n=32,734	Fair to good: high statistical heterogeneity for fasting glucose and weight outcomes; sparse reporting of outcomes beyond 24 months; limited number of trials with significant clinical heterogeneity among physical activity-only counseling trials	Consistent findings of benefit across intermediate health outcomes; trials not included in meta-analyses generally consistent with trials that could be included	Persons with any number of CVD risk factors, no major limitations in populations studied. Medium- to high-intensity combined lifestyle counseling; diet-only counseling mostly in persons with dyslipidemia not yet taking medications	Across all trials reporting each specific outcome, at 12 to 24 months, overall reduction in: <ul style="list-style-type: none"> Total cholesterol (k=34) by 4.48 mg/dL (95% CI, 6.36 to 2.59) LDL cholesterol (k=25) by 3.43 mg/dL (95% CI, 5.37 to 1.49) SBP (k=31) by 2.03 mm Hg (95% CI, 2.91 to 1.15) DBP (k=24) by 1.38 mm Hg (95% CI, 1.92 to 0.84) Fasting glucose (k=22) by 2.08 mg/dL (95% CI, 3.29 to 0.88) Diabetes incidence (k=8) by RR of 0.58 (95% CI, 0.37 to 0.89) Weight outcomes (k=34) by SMD of 0.26 (95% CI, 0.35 to 0.16) Overall evidence for longer-term (>24 months) findings are limited, except for reduction in diabetes incidence in persons with impaired fasting glucose or glucose tolerance (k=5) (RR, 0.55 [95% CI, 0.45 to 0.67]). No consistent finding of benefit on intermediate health outcomes for physical activity-only counseling interventions.
<i>Key Question 3. Behavioral outcomes</i>				
k=61 n=31,751	Fair: heterogeneity in dietary and physical activity outcome measures, mainly use of self-reported outcomes	Generally consistent with intermediate outcome findings	Persons with any number of CVD risk factors, no major limitations in populations studied. Medium- to high-intensity combined lifestyle counseling and diet-only counseling	Generally findings of improvement, or lack of improvement, in behavioral outcomes consistent with findings on intermediate health outcomes. Overall improved dietary intake and physical activity outcomes in trials of persons taking lipid- or blood pressure-lowering medications, which did not demonstrate a benefit on intermediate health outcomes (k=6). Trials only reporting behavioral outcomes (no intermediate outcomes) found small but statistically significant improvements in diet (fat, saturated fat, fiber, fruits/vegetables) and total physical activity (~35–50 minutes more per week) at 12 to 18 months (k=3).
<i>Key Question 4. Adverse effects</i>				
k=10 n=6,381	Fair: sparse reporting of harms	Generally consistent findings of no significant harms	Finding of serious harm applicable to high-intensity physical activity counseling in older adult VA population	Generally no findings of serious harms (i.e., requiring unexpected or unwanted medical attention), except in one trial (n=302) targeting older adults (2 persons with serious adverse events attributed to physical activity). Generally no findings of paradoxical changes in intermediate or behavioral outcomes. Increased self-reported carbohydrate intake accompanied by dietary improvements in fat/saturated fat, fiber, fruits/vegetables without an overall increase in energy intake (k=9).

Appendix A Table 1. Inclusion and Exclusion Criteria

	Include	Exclude
Condition definition	<p>Healthy diet is one designed to improve or maintain optimal health, which includes:</p> <ul style="list-style-type: none"> • Appropriate energy (calorie) content • Balance of fats (consumption of mono and poly unsaturated fats, omega-3 fats, avoidance of excess saturated fat, avoidance of transfat) • Fruits and vegetables • Legumes • Lean proteins • Non- or low-fat dairy • Balance of carbohydrates (consumption of whole grain and fiber, avoidance of excess refined carbohydrates, including excess sweetened beverages) • Balance of sodium (avoidance of excess sodium) <p>Physical activity may involve either:</p> <ul style="list-style-type: none"> • Aerobic activities that involve repeated use of large muscles, such as walking, cycling, and swimming • Resistance training designed to improve physical strength 	<p>Aspects of a healthy diet that are out of scope include:</p> <ul style="list-style-type: none"> • Dietary calcium and other vitamin, micronutrient, and antioxidant supplementation • Alcohol moderation <p>Aspects of physical activity that are out of scope include:</p> <ul style="list-style-type: none"> • Balance • Flexibility • Gait • Sedentary behaviors
Populations	<p>Adults, at least 50% of whom have known CVD risk factors, including hypertension, metabolic syndrome, or impaired fasting glucose, such that >50% of the population is taking medication; mean systolic blood pressure of >140 mm Hg, diastolic blood pressure of >90 mm Hg, LDL cholesterol of >160 mg/dL or total cholesterol >200 mg/dL; or trial inclusion criteria specifies that population has one or more CVD risk factors</p>	<ul style="list-style-type: none"> • Children and adolescents • Parents (if intended behavior change is directed toward children) • Persons with any acute disease (other than hypertension or dyslipidemia) • Persons with known CVD or diabetes mellitus, such that >50% of participants have known CVD, severe chronic kidney disease, or diabetes • Pregnant women with gestational diabetes • Persons in institutions • Persons with severe and persistent mental illness • Persons with cognitive impairment
Settings	<ul style="list-style-type: none"> • Primary care (including obstetrics/gynecology, internal medicine, family practice, military health clinics) or otherwise generalizable to primary care • Trials conducted in countries listed as “high” on the Human Development Index 	<p>Settings not generalizable to primary care (e.g., inpatient hospital units, emergency departments, nursing homes and other institutionalized settings, school-based programs, occupational settings, and other community-based settings); dental clinics</p>

Appendix A Table 1. Inclusion and Exclusion Criteria

	Include	Exclude
Interventions	<ul style="list-style-type: none"> Any behaviorally-based counseling intervention alone or as part of a larger multicomponent intervention on healthy diet and nutrition, physical activity, or both, including ≥1 of the following elements: assessment with feedback, advice, collaborative goal setting, assistance, or arranging further contacts Either conducted in a primary care setting or judged to be feasible in primary care: 1) involves individual-level identification of being a patient or in need of intervention; 2) usually involves primary care physicians, other physicians, nurses, nurse practitioners, physician assistants, or other clinical staff (i.e., nutritionists, dietitians, physiotherapists, health educators), or the intervention will be seen as connected to the health care system by the participant Or must be primary care referable, such that it is available for referral in most communities Limited guided physical activity (i.e., 1 to 2 sessions) or provision of food samples allowed if intention is to teach or demonstrate healthy lifestyle principles Optional or access to guided physical activity or exercises classes allowed 	<ul style="list-style-type: none"> Noncounseling interventions (e.g., use of incentives, supervised exercise with the goal of assessing effects of exercise) Interventions providing controlled diets Counseling interventions aimed at weight loss or weight maintenance, falls prevention, depression, cognitive functioning, or disease prevention other than CVD/diabetes mellitus Prenatal or postnatal dietary counseling Counseling interventions that are primarily community, nonreferral (e.g., occupational/ worksite or school-based); social marketing (e.g., media campaigns) Policy (e.g., local or state public/health policy) Interventions focused exclusively on reducing sedentary behavior (e.g., reduced television or screen time) Interventions that use yoga or tai chi
Comparisons	<ul style="list-style-type: none"> No intervention (e.g., wait-list control, usual care), minimal intervention (e.g., pamphlets, 1 annual session presenting information similar to usual care in a primary care setting), or attention control (e.g., similar format and intensity intervention on a different content area) CG can receive 1 visit annually (limited to 45–60 min) or 2–3 brief sessions annually (limited to 15 min each), but no personalized prescription based on standardized assessment. CG may receive generic print materials twice yearly, but a more extensive print-based workbook would be considered comparative effectiveness and therefore excluded. CGs that received limited feedback on assessments were included 	<ul style="list-style-type: none"> Comparative effectiveness trials without a control (as defined above) Physical activity only: studies in which the CG is instructed not to exercise
Outcomes	<ul style="list-style-type: none"> KQ 1: Distal health outcomes (i.e., morbidity related to CVD, mortality) KQ 2: Intermediate outcomes (i.e., blood pressure, hypertension, total cholesterol, LDL cholesterol or ratio of total/HDL cholesterol, serum fasting glucose or glucose tolerance, hemoglobin A1c, diabetes, weight, body mass index, hyperlipidemia) KQ 3: Behavioral outcomes (i.e., physical activity, dietary intake or dietary patterns), self-reported or objectively measured KQ 4: Adverse outcomes, including any harms requiring medical attention (e.g., nutritional deficiencies, musculoskeletal injuries, cardiovascular events) 	<ul style="list-style-type: none"> Knowledge, attitudes, self-efficacy, functioning, quality of life Physical activity only: studies limited to balance or flexibility outcomes Less than 6 months or 60% followup
Study Designs	<ul style="list-style-type: none"> Fair- to good-quality studies KQs 1–3: Systematic reviews, RCTs, CCTs (RCTs only before 2001) KQ 4: Systematic reviews, RCTs, CCTs, comparative cohorts, population-based case-control studies 	<ul style="list-style-type: none"> Poor-quality studies KQs 1–3: Any observational studies KQ 4: Ecological studies, case-series, case reports

Appendix A Table 1. Inclusion and Exclusion Criteria

	Include	Exclude
Publication Date	Trials published from 1990 to present	Trials whose primary results were published before 1990, in which the interventions were generally conducted in the 1970s

Abbreviations: CCT = controlled clinical trial; CVD = cardiovascular disease; HDL = high-density lipoprotein; KQ = key question; LDL = low-density lipoprotein; RCT = randomized, controlled trial.

Appendix A Table 2. Quality Assessment Criteria

Design	USPSTF Quality Rating Criteria⁶⁰	NICE Methodology Checklists⁶¹
Systematic reviews and meta-analyses	<ul style="list-style-type: none"> • Comprehensiveness of sources considered/search strategy used • Standard appraisal of included studies • Validity of conclusions • Recency and relevance, especially for systematic reviews 	<ul style="list-style-type: none"> • Study addresses an appropriate and clearly focused question • Methodology is described • Literature search is sufficiently rigorous to identify all the relevant studies • Study quality is assessed and taken into account • There are enough similarities between the studies selected to make combining them reasonable
Randomized, controlled trials	<ul style="list-style-type: none"> • Initial assembly of comparable groups employs adequate randomization, including first concealment and whether potential confounders were distributed equally among groups • Maintenance of comparable groups (includes attrition, crossovers, adherence, contamination) • Important differential loss to followup or overall high loss to followup • Measurements are equal, reliable, and valid (includes masking of outcome assessment) • Clear definition of the interventions • All important outcomes are considered 	<ul style="list-style-type: none"> • Study addresses an appropriate and clearly focused question • Assignment of subjects to treatment groups is randomized • Adequate concealment method is used • Subjects and investigators are kept blind about treatment allocation • Treatment and CGs are similar at the start of the trial • Only difference between groups is the treatment under investigation • All relevant outcomes are measured in a standard, valid, and reliable way • Percentage of individuals or clusters recruited into each treatment arm of the study that dropped out before the study was completed is reported • All the subjects are analyzed in the groups to which they were randomly allocated (often referred to as intention-to-treat analysis) • When the study is carried out at more than one site, results are comparable for all sites
Cohort studies	<ul style="list-style-type: none"> • Initial assembly of comparable groups employs consideration of potential confounders, with either restriction or measurement for adjustment in the analysis; consideration of inception cohorts • Maintenance of comparable groups (includes attrition, crossovers, adherence, contamination) • Important differential loss to followup or overall high loss to followup • Measurements are equal, reliable, and valid (includes masking of outcome assessment) • Clear definition of the interventions • All important outcomes are considered 	<ul style="list-style-type: none"> • Study addresses an appropriate and clearly focused question • Two groups being studied are selected from source populations that are comparable in all respects other than the factor under investigation • Study indicates how many of the people asked to take part did so, in each of the groups being studied • Likelihood that some eligible subjects might have the outcome at the time of enrollment is assessed and taken into account in the analysis • Percentage of individuals or clusters recruited into each treatment arm of the study that dropped out before the study was completed is reported • Comparison is made between full participants and those lost to followup, by exposure status • Outcomes are clearly defined • Assessment of outcome is made blind to exposure status • When blinding is not possible, there is some recognition that knowledge of exposure status could have influenced the assessment of outcome • Measure of assessment of exposure is reliable • Evidence from other sources is used to demonstrate that the method of outcome assessment is valid and reliable • Exposure level or prognostic factor is assessed more than once • Main potential confounders are identified and taken into account in the design and analysis • Confidence intervals are provided

Appendix B. Ongoing or Recently Completed Studies

Investigator, Study Name, Location	Number of Participants	Intervention	Outcomes	2013 Status
Dr. Sheldon Tobe HBPS Canada (Heart and Stroke Foundation of Ontario)	5,000	Integrated model in which doctors, nurse practitioners, and pharmacists work together through use of evidence-informed tools, including a patient toolkit addressing lifestyle change information, to control BP in 11 family practice sites	BP	Ongoing
Göteborgs University (no named PI) DIAVIP Sweden	2,000	Diabetes prevention in primary health care, with emphasis on low- vs. high-intensity PA compared with no intervention	HOMA IR	Not yet enrolling
Dr. Denis Pouchain ESCAPE France (College National des Generalistes Enseignants)	1,836	General practice-delivered prevention consultations, focused on diet and exercise, to reduce CVD risk factors in patients with HTN	LDL, HbA1c, BP, PA, diet, QoL, number of targets reached	Completed
Region Skåne (no named PI) The MEDIM Study Sweden	1,244	Lifestyle intervention including group counseling and PA for Iraqi immigrants with prediabetes	FBG, QALY	Not yet enrolling
Dr. Olugbenga Ogedegbe CAATCH Columbia University	1,039	Counseling patients to control HTN using a multicomponent intervention aimed at patients and providers within Community Health Centers	SBP, DBP, cost effectiveness	Completed
Dr. Nancy Kressin Boston University, Boston Medical Center	870	Patient-centered counseling for HTN, with or without cultural competency training for physicians, compared with usual care, to improve control of HTN	BP, % with controlled HTN, medication adherence	Ongoing
Dr. Melanie Davies UK (University Hospitals, Leicester)	804	Group educational program to increase PA and reduce risk for developing diabetes in adults at high risk for diabetes (based on "risk score")	PA, FBG, HbA1c, adiposity (subset)	Recruiting
Dr. Melanie Davies PREVENTION UK (University Hospitals, Leicester)	748	Educational program focusing on lifestyle, PA, and food choices in individuals at high risk for diabetes	Diabetes incidence, FBG, METS, CVD risk, HbA1c	Enrolling
Dr. Esperanza Escortell EDUCORE Spain (Servicio Madrilenos de Salud)	736	Use of the EDUCORE program, a visual aid educational intervention, to improve blood pressure control in patients with hypertension in 22 primary health care centers in Madrid	SBP, DBP, BP control, CVD risk score, TC	Completed
Dr. Beti Thompson Fred Hutchinson Cancer Research Center	430	Education-based, lay health educator-led intervention designed to educate participants with elevated HbA1c levels about diabetes and diet and lifestyle changes	PA, diet, HbA1c	Completed
Dr. Robert Reid FHHP-RCT Canada (University of Ottawa Heart Institute)	426	12-week lifestyle change program for increased exercise and improved nutrition and weight management, with telephone-based motivational counseling in high-risk adults	SBP, TC, HDL, LDL, PA, diet, body composition	Completed
Dr. Robert Nolan I-START Canada (University Health Network, Toronto)	387	Internet-based behavioral counseling for adaptive lifestyle change for subjects diagnosed with hypertension (I-START)	SBP, DBP, PA, diet, vagal-heart rate	Completed

Appendix B. Ongoing or Recently Completed Studies

Investigator, Study Name, Location	Number of Participants	Intervention	Outcomes	2013 Status
Dr. Andrea Kriska Healthy Lifestyle Project University of Pittsburgh	351	DPP-adapted program delivered in a community-based setting. In person vs. DVD session for group lifestyle education focused on weight loss and increasing PA levels for individuals at high risk for diabetes	Weight, BP, FBG, lipids, PA, QoL	Recruiting
Dr. Prabath Nanayakkara WISH The Netherlands (Vrije University Medical Center)	300	Tailored lifestyle advice through Web-based feedback system for adults with hypertension	SBP, DBP	Recruiting
Dr. Gladys Block ALIVE-PD Kaiser Permanente-Northern California, Berkeley Analytics	268	Lifestyle intervention with multichannel delivery, including email/Web goal setting to improve PA, diet and weight loss for patients with prediabetes	FBG, HbA1c, weight, PA, diet	Not yet enrolling
Dr. Robert Zweiker Austria (Medical University of Graz)	256	Structured educational program, including lifestyle and dietary habits, for patients with hypertension	BP, morbidity associated with CVD events	Completed
Dr. Olugbenga Ogedegbe COACH New York University School of Medicine	250	Comprehensive therapeutic lifestyle intervention delivered through group-based counseling and motivational interviewing in seniors with hypertension age 60 years and older	SBP, DBP, PA, weight, diet	Ongoing
Dr. Olugbenga Ogedegbe TLC-Clinic New York University School of Medicine	200	Primary care practice-based lifestyle intervention delivered through group-based counseling and motivational interviewing and focused on PA, diet, and weight management for hypertension	SBP, DBP, PA, diet, weight, sodium	Ongoing
Dr. Antti Jula Finland (National Institute for Health and Welfare)	144	Comprehensive intervention on blood pressure control in a primary care setting, with a focus on lifestyle guidance	SBP, DBP	Completed
Dr. Lena Holm Sweden (Karolinska Institutet)	141	Group seminars and motivational interviewing to change lifestyle factors, including PA and diet, in patients with high blood pressure	BP, PA, diet, BMI, abdominal circumference	Completed
Dr. Theodore Kotchen Medical College of Wisconsin	120	Lifestyle counseling focusing on behavior change for diet and PA to reduce BP in patients with hypertension	SBP, DBP	Recruiting
Dr. Robert Ackermann Northwestern University	92	Group-based adaptation of DPP, delivered by DPP-trained YMCA staff in YMCA facilities	Weight loss, PA, diet	Completed
Dr. Devin Mann ADAPT Mt. Sinai Medical Center, Boston University	80	Use of electronic medical records to enhance lifestyle behavior change counseling in a primary care setting	PA, HbA1c	Recruiting
Dr. Kamlesh Khunti TRIMS UK (University of Leicester)	80	Group education program for individuals with diagnosable METS based on lifestyle changes (diet and increased PA) to decrease risk for diabetes or CVD	METS prevalence, FBG, HDL, BP, PA, Diet, QoL, Framingham risk score	Completed

Appendix B. Ongoing or Recently Completed Studies

Investigator, Study Name, Location	Number of Participants	Intervention	Outcomes	2013 Status
Dr. Namratha Kandula Northwestern University	60	Heart disease prevention group sessions focusing on PA, diet, weight, and stress for adults with at least one CHD risk factor	PA, diet, SBP, DBP, lipids, weight	Recruiting
Dr. Marie-France Longlois Canada (Université de Sherbrooke)	60	Use of interdisciplinary treatment program, including nurse, endocrinologist, nutritionist, and psychologist to discuss diet, PA, and psychological and medication-related issues	METS, weight, diet intake, PA, QoL, cost effectiveness	Completed
Dr. Adam Bernstein FRESH Study The Cleveland Clinic	27	Diet instruction, PA, culinary education, and stress management for patients with prediabetes	Correlation between participation and health of participants	Completed

Abbreviations: BMI = body mass index; BP = blood pressure; CHD = coronary heart disease; CVD = cardiovascular disease; DBP = diastolic blood pressure; FBG = fasting blood glucose; HOMA-IR = homeostasis model assessment insulin resistance; HTN = hypertension; LDL = low-density lipoprotein; METS = metabolic syndrome; PA = physical activity; QALY = quality-adjusted life years; QOL = quality of life; SBP = systolic blood pressure; TC = total cholesterol.

Appendix C. Excluded Studies

This is a listing of studies excluded from the review by key question (KQ). If a study was included for one KQ, but excluded for others, it would still be listed here with the excluded KQs noted.

Exclusion Code
E1. Study relevance a. Does not focus on counseling intervention b. Primary aim is weight loss c. Not focused on cardiovascular disease
E2. Setting a. Human Development Index not >0.9 b. Not generalizable to primary care
E3. Population a. Children, pregnant women, symptomatic patients, ≥50% with coronary heart disease or diabetes b. Biased recruitment or not generalizable to primary care c. Healthy Diet: specialized diet d. Physical Activity: specialized physical activity required e. The majority (≥50%) of participants do not meet high-risk criteria
E4: No relevant outcomes
E5: Not one of the specified interventions a. Yoga or tai chi based intervention
E6: Study design a. Not a trial b. Less than 6 months followup c. Comparative effectiveness d. Physical Activity: CG told not to exercise
E7: Study quality a. Poor reporting b. Problematic baseline comparability c. Unblinded assessment d. High/differential attrition e. Other issues
E8: Precedes search (i.e., main outcomes published before 1990)
E9. Publication not in English

Appendix E. Intervention Descriptions of Included Studies by Intervention Focus and Intensity

Author, Year	Intervention	Description
Edelman, 2006 ¹²⁹	Healthy diet & physical activity counseling	Multidimensional intervention on risk education and development/execution of personal health plan. Risk assessments using the “Know Your Number” tool and individual assessments with medical providers to interpret and understand their risk. Small group sessions: 1) first 7 week phase of the intervention, participants learned about integrative health, explored healthier behavior changes, and developed 1–3 personal health goals to prioritize during the remainder of the intervention; 2) next 21 sessions, participants learned about techniques for changing the behaviors identified in their personal goals. Group sessions included mind-body approaches to self-care, nutritional education, physical activity education, and strategies for behavior change. Individual telephone sessions to reinforce group session techniques, to clarify their priorities and set or update goals, and to enhance their motivation. Two opportunities to meet with a nutritionist for more information and development of an individualized eating plan.
	Usual care	The group received a mailed report including their health assessment and baseline blood test results.
PREMIER, 2003 ¹¹⁶	Healthy diet & physical activity counseling (IG 1)	Participant goals were: 1) weight loss ≥ 15 lb at 6 months for those with BMI ≥ 25 kg/m ² ; 2) ≥ 180 minutes/week of moderate-intensity physical activity; 3) daily intake ≤ 100 mEq of dietary sodium; and 4) daily intake ≤ 1 oz alcohol (2 drinks) for men and $\frac{1}{2}$ oz of alcohol (1 drink) for women. No goals for fruit, vegetable, or dairy intake; saturated fat goal $\leq 10\%$ and total fat goal $\leq 30\%$ of energy. To achieve weight loss, increased physical activity and reduced total energy intake was emphasized. Participants kept food diaries and recorded physical activity.
	Healthy diet & physical activity counseling (IG 2 [DASH diet])	Same goals as IG 1 plus instruction and counseling on the Dietary Approaches to Stop Hypertension (DASH) diet. Goals related to DASH diet were: increased consumption of fruits and vegetables (9–12 servings/day) and low-fat dairy products (2–3 servings/day) and reduced intake of saturated fat ($\leq 7\%$ of energy) and total fat ($\leq 25\%$ of energy). To achieve weight loss, increased physical activity and reduced total energy intake was emphasized (as in IG 1), but IG 2 also emphasized substitution of fruits and vegetables for high-fat, high-calorie foods. In addition to food diaries, recording physical activity, and monitoring calorie and sodium intake (as with IG 1), IG 2 participants also monitored intake of fruits, vegetables, dairy products, and fats.
	Usual care	Interventionist discussed nonpharmacological factors that affect blood pressure (weight, sodium intake, physical activity, and the DASH diet) and provided printed educational materials. Counseling on behavior change not provided.
Nilsson, 1992 ¹¹⁹	Healthy diet & physical activity counseling	Intensive nonpharmacological program for improving knowledge and lifestyle. Run-in period of 1 month with seminars, videotapes, and individual counseling; groups continued to meet monthly and encouraged to meet between sessions. Special physical activity given to all participants and relatives (outdoor walking for 2 hours) and every 2 weeks to the 8 most sedentary men; participation in other sports strongly recommended. Special guided tours to supermarkets as well as cooking instruction and distribution of free olive oil to provide adherence to healthier lifestyle. Goals: low-fat, high-fiber diet recommended; fat energy $< 30\%$, polyunsaturated fat/saturated fat ratio of 0.8/1.0; more mono and polyunsaturated fat; cholesterol < 200 mg/day; fiber 30 g/day (mostly water soluble oat and beans); fruits and vegetable intake; cold water fish (fatty fish such as salmon, mackerel); dietary salt and caloric intake reduced in overweight (BMI ≥ 27 kg/m ²) or increased abdominal obesity distribution; stop smoking; increase physical activity; no overconsumption of alcohol.
	Usual care	No special intervention offered. Told of metabolic disturbances, risk of hyperinsulinaemia, and how to treat it with nonpharmacological methods; opportunity to know findings of 4-day diet recordings.
DPP, 2002 ⁸⁹	Healthy diet & physical activity counseling	Goals were to achieve and maintain weight reduction $\geq 7\%$ of initial body weight through a healthy low-calorie, low-fat diet and engage in moderate-intensity physical activity, such as brisk walking for ≥ 150 minutes/week. Intervention was designed to maximize success by: interactive training in diet, exercise, and behavior modification skills; frequent support for behavior change; interventions that are flexible, culturally sensitive, and acceptable in specific communities where they are implemented; combination of structured protocol and flexibility to tailor strategies individually; and emphasis on self-esteem, empowerment, and social support. Participants taught to record diet and exercise. Offered supervised exercise sessions twice per week for duration of intervention (not mandatory).
	Minimal intervention	Staff reviews written information addressing importance of healthy lifestyle to prevent diabetes with each participant. Encouraged to follow Food Pyramid guidelines and consume equivalent of National Cholesterol Education Program Step 1 diet, lose 5%–10% of initial weight through diet and exercise, increase physical activity gradually to 30 minutes of an activity, such as walking 5 days/week, and avoid excessive alcohol intake. Smokers encouraged to stop smoking. Placebo tablet taken twice per day. Recommendations reviewed annually.

Appendix E. Intervention Descriptions of Included Studies by Intervention Focus and Intensity

Author, Year	Intervention	Description
TONE, 1998 ¹¹⁷	Healthy diet counseling: sodium reduction (IG 1)	Participants advised on ways to change eating patterns. Interventionists provided information using both centrally and locally prepared materials, motivated participants to make and sustain long-term lifestyle changes, monitored individual and group progress at frequent intervals, and helped participants customize intervention to meet individual needs. Centrally prepared materials included food counters, scorekeepers, manuals, and audiovisual aids. Each active intervention consisted of 3 phases (intensive, extended, and maintenance). Primary goal during intensive phase was to provide core knowledge and behavior skills necessary to achieve and maintain reductions in sodium and body weight. During extended phase, focus was on problem solving and relapse prevention. During maintenance phase, continued attempts made to maintain or reengage participant interest in the intervention. Goal was 24-hour dietary sodium intake ≤ 1800 mg (as measured by 24-hour urine collection).
	Physical activity counseling: weight loss (IG 2)	Participants advised on ways to increase physical activity for weight loss. Goal was weight loss ≥ 4.5 kg (10 lb).
	Healthy diet & physical activity counseling: sodium reduction & weight loss (IG 3)	Combination of IG 1 & IG 2. Participants advised on ways to change eating patterns (all active interventions) and increase physical activity (weight loss interventions).
	Usual care (partial attention control)	Usual care groups received no study-related counseling in lifestyle change techniques, but were invited to meetings on topics unrelated to diet, physical activity, and cardiovascular disease.
HIP ¹³⁶	Healthy diet & physical activity counseling: patient only (IG 1)	Weekly small group sessions focusing on behavior change using the following strategies: frequent contact, group interaction and social support, goal setting and self-monitoring, identification of barriers and problem solving, and motivational interviewing. Participants kept records of dietary intake, physical activity, and medication use. Group sessions and the participant manual emphasized diet, physical activity, and changing behaviors. Community health advisors attended and helped to lead group sessions and also provided 1-on-1 telephone counseling during and after the group session period.
	Healthy diet & physical activity counseling: patient + physician (IG 2)	Same as above, plus physician-focused training. Physician: training modules (CME) aimed at JNC-7 guidelines and lifestyle modification for blood pressure control. An evaluation and treatment algorithm summarizing the major JNC-7 guidelines and formatted as a decision tree was provided to each physician. Assessment and quarterly feedback to physicians on their adherence to guidelines, including lifestyle counseling that assessed the proportion of patients with hypertension whose blood pressure was controlled, proportion not at goal, proportion that received lifestyle counseling, proportion with diabetes or chronic kidney disease who were at goal blood pressure and prescribed a thiazide diuretic or angiotensin-converting enzyme inhibitor/angiotensin receptor blocker, and comparisons of physicians with peers.
	Usual care	Patients: brief visit after randomization during which they received advice and brochures on lifestyle modification for blood pressure control consistent with JNC-7 guidelines.
PREDIAS, 2009 ⁹⁵	Healthy diet & physical activity counseling	Group sessions (median size, 7 people) based on the self-management approach. PREDIAS goals were: weight loss (minimum 5%), change of unhealthful eating habits, and increase in physical activity to >150 minutes/week. First 8 weeks were comprised of weekly core lessons covering 8 topics: motivational challenge, weight reduction, healthy diet, analysis and modification of eating habits, physical activity, analysis and modification of physical activity, social support, and maintenance of lifestyle modification. Booster session topics included: dealing with failure, stress management, activating resources, and maintaining new lifestyle. Group leaders provided with curriculum and patients were given a book that contained information about diabetes prevention, resources, and worksheets for each lesson (i.e., eating diaries and physical activity logs).
	Minimal intervention	Controls received the PREDIAS written group information and written patient materials.

Appendix E. Intervention Descriptions of Included Studies by Intervention Focus and Intensity

Author, Year	Intervention	Description
FDPS, 2001 ¹¹⁸	Healthy diet & physical activity counseling	Goals of the intervention were: weight reduction $\geq 5\%$; fat intake $< 30\%$ of energy; saturated fat intake $< 10\%$ of energy (mono or polyunsaturated fats, 20% of energy, or $\leq 25\%$ if surplus from monounsaturated fat); cholesterol < 300 mg/day; 1.0 g protein per kg ideal body weight per day; carbohydrate intake $> 50\%$ of energy; increase fiber to ≥ 15 g/1,000 kcal; and moderate exercise for ≥ 30 minutes/day. Frequent ingestion of whole-grain products, vegetables, fruits, low-fat milk and meat products, soft margarines, and vegetable oils rich in monounsaturated fats recommended. Dietary advice tailored to each subject on the basis of 3-day food records completed 4 times/year. Subjects received individual guidance on increasing physical activity. Endurance exercise (e.g., walking, jogging, swimming, aerobic ball games) was recommended. Optional supervised, progressive, individually tailored, circuit-type resistance-training sessions offered up to twice per week (participation rates varied from 50%–85% at different centers).
	Usual care	General nontailored verbal and written advice (2-page leaflet) to adjust total energy intake in order to reduce BMI to < 25 kg/m ² ; keep fat to $< 30\%$ of daily energy; reduce alcohol intake; and stop smoking as appropriate. Verbal general information about health effects of recreational exercise provided, but no specific individual advice given.
LLDP, 2012 ⁹⁴	Healthy diet & physical activity counseling	Increasing intake of whole grains and nonstarchy vegetables and reducing sodium, total and saturated fat, portion sizes, and refined carbohydrates and starches. The physical activity goal was to increase walking by 4,000 steps per day from baseline. Participants received a pedometer. Skill building included cooking classes, shopping skills, goal setting, self-monitoring, problem solving, and information on opportunities to engage in safe physical activity. The previous DPP intervention was tailored to be culturally and low-literacy sensitive by focusing on traditional Latino foods, using a video series featuring Latino actors, and illustrated, colorful workbooks and materials.
	Usual care	No description provided.
Inter99, 2008 ¹⁰⁷	Healthy diet & physical activity counseling	Three kinds of group counseling offered: a smoking cessation course, a smoking reduction course, and a course on diet and physical activity. Choice of group depended on risk factors and the preference of the individual. Those who were not ready to decide if they wanted to participate in group counseling were encouraged to consider the invitation and were contacted by mail after 3 months and offered participation in a group. Relatives of participants were offered to participate in 1 of the meetings. After 1 and 3 years, individuals still fulfilling high-risk criteria were again offered group counseling. Group counseling included didactic and open-ended discussion and committing to specific diet and physical activity goals; dietary and physical activity advice mirrored advice in individual sessions. In group sessions, the physical activity aim was to achieve small positive changes in physical activity in everyday life.
	Minimal intervention	Based on a personal risk assessment, each participant received an individual “lifestyle counseling talk” focusing on smoking, physical activity, diet, and alcohol. Counseling addressed all individuals who smoked, had < 30 minutes physical activity daily, had a high saturated fat diet, < 300 g fruits/vegetables daily, or alcohol consumption > 14 drinks/week for women and > 21 for men. Written materials provided as appropriate. Overall goal was to achieve small but sustained dietary changes. Specifically, decreasing total saturated fat intake, substituting saturated for unsaturated fat, and increasing intake of fruits/vegetables and fish. Participants advised to aim for 4 hours/week of physical activity (some papers report 30 minutes/day); only minimal counseling time spent on physical activity. Participants reinvited after 1 and 3 years for risk assessment and counseling and at 5 years for a short final lifestyle counseling session.
PEGASE, 2008 ¹²⁰	Healthy diet & physical activity counseling	Assessment and counseling for healthy diet and physical activity. Sessions focused on 3 stages: increasing awareness on CVD risks, start action, and maintain action. Group sessions included self-reflection on risks and threats to health, physical activity and healthy diet education, and information on cholesterol management, plus written materials. Educational messages were reinforced during individual sessions, along with focusing on translating individual goals into small, achievable steps and actions related to healthy behaviors.
	Usual care	Physicians received no training; patients received usual care.
Applegate 1992 ¹²⁷	Healthy diet & physical activity counseling	Focused on calorie and sodium restriction and increase in moderate levels of physical activity. Weight loss goal was 4.5 kg and calorie restrictions were individualized (women advised to not eat < 1200 calories per day and men not < 1500). Daily sodium consumption was reduced to 1400 mg. Advised to increase physical activity to 120 minutes/week.
	No advice	Received no treatment; if diastolic blood pressure exceeded 105 mm Hg, participants were placed on medication and removed from trial.

Appendix E. Intervention Descriptions of Included Studies by Intervention Focus and Intensity

Author, Year	Intervention	Description
EDIPS-Newcastle, 2009 ⁹¹	Healthy diet & physical activity counseling	Counseling sessions included individually tailored plans for behavior change with the following goals: >50% energy from carbohydrates, <30% energy from fat, reduce saturated fat, increase fiber intake, and physical activity of 30 minutes of moderate aerobic activity each day. Weight goal was BMI <25 kg/m ² . Three-day food diaries, activity diaries, weight, and waist circumference used to track behaviors. Group sessions included healthy cooking demonstrations and tastings and healthy behavior education. Quarterly newsletters were mailed and included information on healthy recipes, nutrition labels, and opportunities for exercise in the community. Information packs with information about local exercise facilities and opportunities, along with a City Card (offering discounts on facilities), and the opportunity to meet with a trainer for an initial session were offered.
	Usual care	Standard advice plus widely available educational leaflets on healthy eating and physical activity.
APHRODITE, 2011 ⁸⁸	Healthy diet & physical activity counseling	Stages of change-based intervention with the following goals: weight reduction ≥5% if overweight; moderate- to high-intensity physical activity ≥30 minutes, 5 days/week; fat <30% of energy; saturated fat <10% of energy; and dietary fiber intake ≥3.4 g/MJ. A 3-day food record informed a dietician consultation.
	Usual care	Received oral and written information about type 2 diabetes, risk for developing diabetes, and benefits of exercise and healthy diet.
WISEWOMAN NC, 2008 ¹¹⁰	Healthy Diet & physical activity counseling	Individual sessions consisted of education about barriers to behavior change and "tip sheets" were used to facilitate tailored messaging. An action plan with 2–3 specific goals related to healthy diet and physical activity was created in the first session and progress was monitored at each subsequent session. A motivational videotape was given to view at home. Group sessions focused on teaching problem solving skills, lifestyle behavior change strategies, and emphasized the importance of social support. Education regarding heart-healthy eating, portion sizes, meal planning, and how to read nutrition labels also included. Group sessions also included recipe taste testing and 15-minute physical activity sessions (chair exercises). Food and exercise diaries and pedometers were used to track activity and diet. Participants received monthly phone calls offering support, followup on goal setting, and linkages to community resources.
	Usual care	One-time mailing of two AHA pamphlets on healthy dietary and physical activity practices.
SLIM, 2011 ¹⁴⁹	Healthy diet & physical activity counseling	Diet: dietary goals based on Dutch guidelines and included carbohydrate intake ≥55% of total energy; total fat intake <30%–35% of total energy, with <10% total energy intake of saturated fats; cholesterol intake <33 mg/MJ; protein intake 10%–15% total energy, and dietary fiber intake ≥3 g/MJ. Weight loss goal was 5% to 7%, depending on the degree of obesity. Initially, this was achieved by stimulating people to change their daily dietary intake and increase physical activity according to recommendations. If necessary, subjects received example of a mild energy-restricted diet during second year. Detailed dietary advice based on 3-day food record. At each meeting, new goals (including physical activity) were set for the next visit. Topics covered in sessions included fat, carbohydrates, label reading, artificial sweeteners, special occasions, vegetarian food, vitamins and minerals, and lifestyle and diabetes. Physical activity: physical activity goal was to increase low- to moderate-physical activity to ≥30 minutes/day, 5 days/week. Individual advice was given on how to increase daily physical activity. Participants were offered supervised training sessions as part of an exercise program designed for the study that emphasized aerobic exercise and resistance training. Subjects had free access to training sessions and were stimulated to participate for ≥1 hour/week.
	Usual care	Oral and written information on healthy diet, weight loss, and increased physical activity. No individualized advice or information provided.
Migneault, 2012 ¹²⁶	Healthy diet & physical activity counseling	Telephone-linked care: automated system delivered 3 tailored behavior intervention modules using social cognitive theory, transtheoretical model of behavioral change, and motivational interviewing. The first 3 calls introduced targeted behaviors, how they help with blood pressure control, and oriented users to the system. Subsequent calls were modules on medication adherence (8 calls), physical activity (12 calls), and diet (9 calls). The physical activity module focused on increasing moderate- or greater-intensity physical activity. The diet module focused on fruits/vegetables, fiber, sodium, and fat and intended to promote the DASH diet. Participants and their providers received printouts of their tracked health behaviors. Before randomization, all eligible participants had an in-home visit for health education (and to collect baseline data).
	Minimal intervention	Pre-randomization, everyone had 1 visit for health education; a 75-page resource manual that described hypertension, dietary recommendations, food recipes, and local resources for exercise; and support for medication adherence; also received a pedometer and digital scale. Followed by usual primary care, details not reported.

Appendix E. Intervention Descriptions of Included Studies by Intervention Focus and Intensity

Author, Year	Intervention	Description
Kosaka, 2005 ⁹³	Healthy diet & physical activity counseling	Individual advice was given to help patients lower their BMI if it was above the desirable range for Japanese men (≥ 22 kg/m ²). Patients were instructed to weigh themselves at home weekly. Patients were given instructions based on their current dietary habits to help them achieve a BMI of 22 kg/m ² . Patients were encouraged to maintain a nutrient balance, to eat smaller portions, and to consume less fat, alcohol, and fewer meals outside the home. Dietary recommendations were based on "Food Exchange Lists, Dietary Guidance for People With Diabetes." Current physical activity was assessed and realistic ways of achieving a physical activity goal of 30–40 minutes per day were discussed.
	Minimal intervention	All participants were informed of the importance of maintaining a healthy lifestyle. CG subjects with BMI ≥ 24 kg/m ² were advised to reduce their portion sizes and increase physical activity. Those with BMI < 24 kg/m ² were told to maintain their current weight. These objectives were repeated at each hospital assessment visit.
EURO-ACTION, 2008 ¹⁰⁶	Healthy diet & physical activity counseling	Encouraged to achieve a healthy lifestyle with support from family and health professionals using stages of change and motivational interviewing. Advice provided in terms of food (not nutrients) and patterns of eating and set realistic goals for patients and their families. No supervised exercise classes; physical activity plan developed with goals, step counter used for motivation. For smoking cessation, prepared, set date, and made contingency plans. Workshops focused on lifestyle and risk factors. Goals: not smoking, saturated fat $< 10\%$ total daily energy, fruits/vegetables > 400 g/day, fish > 20 g/day, oily fish > 3 times/week, alcohol < 30 g/day, BMI < 25 kg/m ² , waist circumference < 81 cm for women and < 95 for men, 30–45 minutes moderate-intensity physical activity 4–5 times/week, blood pressure $< 140/90$ mm Hg ($< 130/85$ mm Hg in diabetics), total cholesterol < 5.0 mmol/L, low-density lipoprotein < 3.0 mmol/L, blood glucose concentration < 6.1 mmol/L (good glycemic control in diabetics); for BMI ≥ 25 kg/m ² , reduce weight by 5% in 1 year.
	Usual care	No details provided.
LIHEF, 2002 ¹³⁷	Healthy diet & physical activity counseling	Individualized counseling focused on changing health behaviors, specifically reducing sodium to < 5 g/day, reducing saturated fat consumption, and consuming ≤ 2 alcoholic beverages per day; increasing physical activity to ≥ 3 sessions of 30-minute, moderate-intensity activity per week; and smoking cessation. Weight reduction was also emphasized (goal of BMI < 25 kg/m ²). Participants recorded food consumption in 4-day food diaries. Group sessions concentrated on reducing salt intake and body weight.
	Usual care	Instructed to see their primary care physician according to usual care practices.
HLC, 2011 ⁹²	Healthy diet & physical activity counseling	Pre-course individual session in which personal medical history, eating, and exercise patterns are discussed. Group psychoeducational learning sessions on diet, physical activity, motivation, goal setting, stress, and support to adopt healthier lifestyle choices.
	Waitlist control	Waitlist control. CG was not restricted in their use of usual health care services.
RIS, 1998 ¹¹²	Healthy diet & physical activity counseling	Aims to reduce total cholesterol to < 6.0 mmol/L, help current smokers quit, prevent nonsmokers from starting, reduce HbA1c to $< 6.0\%$ in diabetics, and lower diastolic blood pressure to < 90 mm Hg. Weekly lessons for 5 weeks for 10–20 patients (and spouses) to change eating habits; basic nutrition, purchase and preparation food book, slide series, textbooks, and food/beverage exhibition. Overweight patients set a weight goal. Restriction of alcohol intake for high consumers; diabetics taught self-monitoring glucose; all provided physical activity information. Followup visit with nurse to discuss results and further changes in dietary habits. Smoking cessation include discussion of smoking habits, symptoms of and diseases secondary to nicotine usage, psychological and social factors, and motivation for quitting.
	Usual care	Usual care. Primary care physician treated hypercholesterolemia, diabetes, and smoking according to normal practice.
ADAPT, 2006 ¹³⁸	Healthy diet & physical activity counseling	Multifactorial program aimed at reducing need for antihypertension drugs and decrease cardiovascular risk factors; focused on DASH diet for dietary advice: sodium intake < 2 g/day; increased intake of fruit, vegetables, and low-fat dairy; reduced intake of total saturated fats, sweets, and sugary drinks; consuming ≥ 4 fish meals per week; participating in ≥ 30 minutes of physical activity most days; weight loss (reducing weight by $\geq 5\%$); reduced alcohol (consuming ≤ 2 drinks/day), and smoking cessation. Social support was encouraged by allowing a partner, relative, or friend to accompany participants during group sessions and involving them in grocery shopping, meal preparation, and physical activity. Diet and physical activity calendars were used to track behaviors.
	Usual care (partial attention control)	Usual care; publications from the National Heart Foundation of Australia and the Health Department of Australia; attention control with 4 seminars on topics unrelated to the trial were held as well.

Appendix E. Intervention Descriptions of Included Studies by Intervention Focus and Intensity

Author, Year	Intervention	Description
HTTP, 1993 ¹³⁴	Healthy diet & physical activity counseling	Intervention objectives are: assumption of greater responsibility for disease management, including blood pressure self-monitoring and treatment decisionmaking; confirming diagnosis of hypertension and treatment using at home blood pressure monitoring; and emphasis on nonpharmacological treatments. First session focuses on group discussions and patients are provided with blood pressure monitors and log books. Second session, blood pressure monitoring and log books are assessed, and strategies for achieving blood pressure control (including dietary and physical activity recommendations) are discussed. The last 2 sessions focus on antihypertension therapy.
	Minimal intervention	Staff and medical doctors at all practices were also trained in blood pressure measurement techniques to increase frequency of blood pressure measurements. Additionally, 20 patients at each site had their medical files marked with a red dot to remind clinic staff to take blood pressure, weight, and medication information at each visit. Control practices continued to treat hypertensive patients without the HTTP program; after the study these practices could initiate the program. In the CG, only the physician and staff training occurred, in the IG, both physician and staff training occurred plus the group HTTP intervention.
Hyman, 2007 ¹³⁵	Healthy diet & physical activity counseling (IG 1)	Motivational interviewing plus home-based instruction manual to improve adherence to lifestyle behaviors for reducing CVD risk. Primary goals for target areas included: stop smoking, reduce sodium levels to <100 mEq/L/day, and increase physical activity by 1500 steps/day (or >10,000/week); were measured objectively in all areas. Six-month visits included measurements; postcard was mailed to participants to report how their measures compared to goals. IG 1: Simultaneous counseling addressed all 3 behaviors during the 6 months. Counseling interaction and instruction manual.
	Healthy diet & physical activity counseling (IG 2)	Same content as above, but sequential counseling introduced 1 area at a time at each 6-month interaction (all 3 areas addressed over 18-month period, in random order), plus instruction manual.
	Minimal intervention	Brief educational session on 3 target behaviors (smoking cessation, sodium intake reduction, increased physical activity). Postcards mailed after each 6-month measurement to report how measures compared to goals.
Logan Healthy Living, 2009 ¹¹⁴	Healthy diet & physical activity counseling	Telephone counseling focusing on motivational interviewing to promote healthy diet and physical activity. Patients were mailed a workbook and pedometer. Counseling followed the "4A" approach: assessment, advice, assistance, and arranging followup. Advice was consistent with Australian National Guidelines and physical activity goal was 150 minutes/week of moderate-intensity physical activity. Consultations were not tailored to diabetes or hypertension, but healthy diet and physical activity suggested were appropriate for both conditions. Calls were weekly at first and moved to biweekly.
	Minimal intervention	After each assessment, minimal intervention patients received a brief and tailored letter with feedback. They also received generic brochures on a variety of health topics.
RHPP ⁶⁹	Healthy diet & physical activity counseling: hospital-based (IG 1)	2 IGs: hospital-based (IG 1) and physician-based (IG 2). Both had initial Health Risk Appraisal with 5 vouchers for free health screenings and health promotion services related to identified risk factors. IG 1 offered health screening and health promotion services through regional hospitals.
	Healthy diet & physical activity counseling: physician-based (IG 2)	IG 2 offered the same services through participating primary care clinics. Seven possible risk factor interventions, ranging from weight management to flu immunizations. Educational mailings on lowering cholesterol were distributed to participating providers; offered education sessions by dietitians covering government/society recommendations (AHA, NHLBI, NCEP) for lowering cholesterol; physician training on lowering cholesterol was offered in the area.
	Usual care	Usual care; not offered vouchers for screening or health education.

Appendix E. Intervention Descriptions of Included Studies by Intervention Focus and Intensity

Author, Year	Intervention	Description
Rodriguez-Cristobal, 2012 ¹⁷²	Healthy diet & physical activity counseling	With the support of their physicians and psychologists, patients received specific interventions using different measures to help improve their habits. Smoking: motivated to give up smoking and received clear and tailored advice as well as medication when indicated. Physical activity: advice to start, maintain, or increase current level of physical activity. Obesity or overweight: gradual weight loss (methods not reported) and maintaining a healthy diet after healthy weight achieved. Weight objective: BMI 20–25 kg/m ² . Hypertension: dietary and pharmacological treatment according to guidelines. Hypertension objective: physical activity <140/90 mm Hg; diabetics <130/80 mm Hg. Diabetes: dietary or pharmacological treatment according to guidelines. Diabetes objective: HbA1c <7%. Psychologists made phone calls to remind IG of upcoming visits (every 2 months) and to provide encouragement about maintaining lifestyle changes.
	Usual care	Received information about their lifestyle according to current practice guidelines.
Bo, 2007 ¹⁴⁶	Healthy diet & physical activity counseling	General healthy lifestyle information from their physicians (see details in CG description), plus the following: 1) an individually-prescribed diet tailored to their current weight and dietary intake; general dietary recommendations about cooking, reducing fat, sugar, and salt intake, and tips for dining out; written recommendations for physical activity; brief written guide on behavioral change; copy of the Food Pyramid; explanations about the benefits of using diet and exercise to control metabolic abnormalities; and individualized diet and physical activity goals; 2) group sessions on 4 different topics: food composition, portion control, strategies for dining out, and physical activity benefits.
	Usual care	General information on the importance of a healthy lifestyle. Physicians gave advice according to their usual practice and had participated in ≥3 meetings on standard practice lifestyle recommendations and the efficacy of preventive lifestyle changes. No written information or recommendations were given.
CouPLES, 2013 ⁹⁷	Healthy diet & physical activity counseling	Phone intervention targeting diet, physical activity, patient-physician communication, and medication adherence to improve cholesterol control; patients and spouses received information about hypercholesterolemia and an overview of self-management principles; spouses also received an orientation to strategies to support patient goal achievement; patient calls focused on goal setting and problem solving, patients selected their own goals. Patients were able to select 1 of 4 topic modules (diet, physical activity, medication adherence, patient-physician communication); first spouse call focused on learning about the patient's goals and action plans and strategies to help the patient; subsequent followup monitoring of patient progress and modifying or creating new goals and action plans; second spouse call focused on staying informed on patient progress and learning about new goal suggestions to help patients; plus mailed printed materials.
	Minimal intervention	Clinical management of lipid disorders using ATP III guidelines. Reminders for physicians were embedded in 11 emails and electronic medical records. Emails emphasized the use of lipid-lowering medications. Physicians also had access to referral specialty clinics (lipid disorders clinic, risk factor management clinic for high-risk patients)
EDIPS, 2006 ¹⁷⁷	Healthy diet & physical activity counseling	Regular counseling using stages of change. Included a dietary assessment using baseline food diary. Stage-specific motivational interviewing was used to develop individual targets for behavior change. Participants were encouraged to eat healthy according to British Diabetic Association recommendations (fat 30% of energy, carbohydrates 50%–55% of energy, polyunsaturated/saturated fats ratio of 1.0, daily dietary fiber 20 g/1000 kcal). Participants were given written nutrition education materials. Level of physical activity was assessed and a graded physical activity plan was tailored to participant's lifestyle (designed to enable 20–30 minutes of aerobic activity 2–3 times/week). Information about exercise facilities was provided and a discount card for public leisure facilities in the city was offered to all participants.
	No advice	No advice.
PHPP, 2007 ¹²¹	Healthy diet & physical activity counseling	Team encouraged patients to set their own goals and select lifestyle improvements that they were interested in making; choose and prioritize physical activity to achieve goals; provided advice about how to achieve goals using "stages of change" challenge cards. Problem solving for ways to achieve goals, or discussion about changing goals when appropriate, was part of sessions.
	Usual care	Asked to return to the medical center 1 month after baseline assessments, where they received results and were given instructions on how to enhance physical activity via leaflets only.

Appendix E. Intervention Descriptions of Included Studies by Intervention Focus and Intensity

Author, Year	Intervention	Description
Rodriguez, 2012 ¹¹³	Healthy diet & physical activity counseling	Telephone counseling based on transtheoretical model for exercise, diet, and medications, based on patient's current stage of change. Stage of change was evaluated at each session and a computer system was used to deliver standardized interventions; problem solving; tips and information for each behavior; and review of medication log (a calendar tracked medication use).
	Minimal intervention (CG 1)	Nontailored health education telephone calls about hypertension management and other health topics. General information was provided about hypertension, sun safety, flu prevention, sleep hygiene, preventing back injury, and vision/hearing problems.
	Usual care (CG 2)	Participated in in-person assessment visits only.
Hardcastle, 2008 ¹⁶⁷	Healthy diet & physical activity counseling	Stage-matched motivational interviewing approach in which the focus on diet or physical activity depended on the participant's priorities and readiness to change.
	Usual care	All patients received a standard leaflet about exercise and nutrition at their baseline assessment.
GOAL, 2009 ¹³⁹	Healthy diet & physical activity counseling	Initial lifestyle questionnaire followed by physical activity and healthy diet counseling consisting of individual sessions focused on self-awareness, lifestyle education, individual motivation, and goal setting. Patients developed a tailored treatment plan based on goals. Ongoing evaluation of goals by nurse practitioners during sessions; modification of goals, as needed, as well as possible referral to dietician. Diet was assessed via food diaries and physical activity was measured using pedometers.
	Usual care	1 session (10 minutes) to discuss results from screening, followed by usual care.
WISEWOMAN California, 2010 ¹⁰⁸	Healthy diet & physical activity counseling	Assessment and counseling for healthy diet and physical activity. Individually tailored; comprised of collaborative goal setting, identifying strategies for overcoming barriers, and outlining small, achievable steps. Emphasis on self-efficacy, self-monitoring, reinforcement, readiness for change, and importance of social support. Delivered in language of choice. Visual aids and hands-on tools used (e.g., food models showing appropriate portions), along with a curriculum binder. Community health workers followed up via telephone in between sessions to encourage healthy behaviors, give referrals to health education classes (e.g., smoking cessation, nutrition, physical activity), and give appointment reminders. Received incentives (e.g., tote bags, water bottles, transportation tokens, grocery store vouchers) during assessments and sessions.
	Usual care	Usual care for elevated blood pressure and cholesterol. May have included brief healthy behavior education, healthy lifestyle handouts (general, related to hypertension/hyperlipidemia), or referral to education classes. Received incentives during assessments.
Wister, 2007 ¹⁴⁰	Healthy diet & physical activity counseling	Report card to patient and primary care physician with risk profile and telehealth self-management system; recommendations based on letter grade score for each key lifestyle or Framingham risk factor. Telephone counseling used staged target levels developed for each patient. Smoking was considered the top priority for lifestyle counseling, followed by physical activity, dietary habits, weight management, and stress. A counselor addressed areas in which the grade was lowest first. Comparisons with previous report cards were discussed with the participant to set new goals. Summaries of each counseling session and supporting evidence were mailed to the participants.
	Usual care	Received usual care from their physicians, based on their own determination of the need for visits.
Vitalum, 2011 ¹⁰⁵	Healthy diet & physical activity counseling (IG 1)	Four tailored letters based on baseline and followup survey data (variables included current behavior, awareness, age, sex, stage of change, attitude, self-efficacy expectations, and action plans); letters 1 & 3 focused on physical activity (3–6 pages) and 2 & 4 on fruit/vegetable consumption (4–6 pages). Half in each group received pedometers at week 29 (along with instructions to gradually increase their number of steps to 10,000/day), and the remainder received it after the last followup.
	Healthy diet & physical activity counseling (IG 2)	Four telephone calls based on motivational interviewing about physical activity and fruit/vegetable consumption. Half in each group received pedometers at week 29 (along with instructions to gradually increase their number of steps to 10,000/day), and the remainder received it after the last followup.
	Healthy diet & physical activity counseling (IG 3)	Combined methods from IG 1 and 2; 2 tailored print letters and 2 telephone motivational interviews. 1 letter and 1 call focused on physical activity; the other 2 focused on fruit/vegetable consumption. Half in each group received pedometers at week 29 (along with instructions to gradually increase their number of steps to 10,000/day), and the remainder received it after the last followup.
	Usual care	After the intervention periods, received 1 tailored letter addressing physical activity and fruit/vegetable consumption based on participants previous followup questionnaire.

Appendix E. Intervention Descriptions of Included Studies by Intervention Focus and Intensity

Author, Year	Intervention	Description
IMPALA, 2009 ¹³³	Healthy diet & physical activity counseling	To implement a nurse-led cardiovascular risk management program, nurses received a 2-day training focused on 4 strategies: risk assessment, risk communication, use of decision aids, and adapted motivational interviewing. Counseling emphasized resolving ambivalence about behavior change, increasing patient motivation to improve healthy behaviors, self-directed goal setting, and creating concrete action plans. Nurses explained 10-year CVD mortality risk score and used a risk communication tool, which was given to patients. Risk reduction techniques were explained and decision aids were given to patients to review at home. Agenda-setting charts were used to allow patients to guide discussion at each meeting.
	Usual care	Nurses received a 2-hour training on risk assessment. Nurses assessed 10-year CVD mortality risk using table from Dutch guidelines (for those without diabetes) or the UK Prospective Diabetes risk engine (for those with diabetes); patients received usual care after risk assessment step.
Arroll, 1995 ¹²⁸	Healthy diet & physical activity counseling (IG 1)	Exercise and salt interventions. All participants kept a weekly diary tracking injuries or health problems and medication compliance.
	Healthy diet & physical activity counseling (IG 2)	Exercise: advised to walk briskly for 40 minutes 3 days per week. A plan to build up to this amount of exercise was determined by the patient's doctor.
	Healthy diet & physical activity counseling (IG 3)	Salt: asked to decrease use of high-salt foods and added salt when cooking and eating. Each person received a simple pamphlet, a general article about salt and blood pressure, and an in depth book with information about salt content of common foods.
	Usual care, partial attention control	Usual care; publications from the National Heart Foundation of Australia and the Health Department of Australia; attention control with 4 seminars on topics unrelated to the program were held as well.
Bosworth, 2009 ⁸⁴	Healthy diet & physical activity counseling (IG 1)	Tailored behavioral self-management intervention. Nurse delivered bimonthly telephone calls. Information presented in an easily understood format with a readability score of 9th grade or less. Factors targeted in calls were: perceived risk for hypertension, memory, literacy, social support, patients' relationships with their healthcare provider, and side effects of medication. Intervention also focused on improving adherence to the DASH diet, weight loss, reduced sodium intake, regular moderate-intensity physical activity, smoking cessation, and moderation of alcohol intake. Each encounter included a core group of modules potentially implemented during each call and additional modules activated at specific intervals.
	Healthy diet & physical activity counseling (IG 2)	Combined intervention. Nurse-led telephone intervention as described above, as well as receipt of a home blood pressure monitor and training on its use. Trial nurse was not aware of home-monitored blood pressure values, but participants asked to maintain and turn in blood pressure logs.
	Usual care	Hypertension treatment from regular provider.
Cochrane, 2012 ¹⁰²	Healthy diet & physical activity counseling	NHS Health Check plus support for lifestyle change. Lifestyle change based on national Health Trainer motivational interviewing/counseling model. Sessions with lifestyle coach provided opportunity to discuss goals and make a plan. Also, referrals to support sessions for weight management, physical activity, cooking and eating, and positive thinking, as desired by participant. Additional individual support was provided for first 20 weeks of program and ongoing support was available up to 1 year.
	Minimal intervention	NHS Health Check plus usual general practice care, including medication or treatment for elevated blood pressure, cholesterol, and newly diagnosed diabetes and referral to smoking cessation services, but did not receive additional lifestyle support. May have received lifestyle advice from the general practitioner team.

Appendix E. Intervention Descriptions of Included Studies by Intervention Focus and Intensity

Author, Year	Intervention	Description
E-LITE, 2013 ⁹⁷	Healthy diet & physical activity counseling	Self-management group. IT-assisted self-management lifestyle intervention. Based on social cognitive theory and transtheoretical model of behavior change and focuses on goal setting, skill building, and self monitoring to instill behavior change. Participants attend 1 group session where they were trained to track their weight and physical activity using the AHA online self-management portal and given a scale and pedometer. Introductory session was followed by a 12-week curriculum ("Group Lifestyle Balance") on a DVD developed by DPP (for home use) and access to a study dietitian via secure, online messaging. Participants are given primary goal of 7% weight loss and 150 minutes of moderate physical activity per week, within 5 weeks of initiating intervention. Other goals include total fat reduction (25% of calories from fat) and calorie restriction (reduction of 500 to 1000 calories); lower saturated fat intake; lower cholesterol intake; consume a high plant-based diet (fruits, vegetables, whole grains, low-fat dairy); reduce intake of high glycemic index carbohydrates. After attaining the physical activity goal, participants who wish to be more active (or who have not achieved the weight loss goal) are encouraged to increase their physical activity levels. Three-month intensive phase followed by 12 months of maintenance.
	Usual Care	Primary care physician for usual care.
HIPS, 2012 ¹⁰³	Healthy diet & physical activity counseling	Physician intervention modeled after SNAP intervention; brief intervention based on the stages of change and 5A models. Physicians were trained in assessing risk factors and motivational interviewing. Patient education resources (waiting room questionnaires, health check visit guides, physician checklists) were available. Patients attended individual counseling sessions if deemed high-risk by the brief intervention. High risk was defined by any 1 of the following: history of diabetes or impaired fasting glucose or glucose tolerance; hypertension; dyslipidemia; BMI >25 kg/m ² ; waist circumference >102 cm in males or >88 cm in females; or current smoker. Food diary was assessed and individually-tailored lifestyle goals were developed. Group sessions included health education on self-management strategies and physical activity (20–30 minutes of walking or resistance exercise). Between sessions, patients kept food and exercise diaries, used a pedometer, and participated in home-based exercise.
	Waitlist control	Usual care; after 12 months, control practices offered to join intervention.
HOORN, 2013 ¹³²	Healthy diet & physical activity counseling	Based on the theory of planned behavior and self-regulation; aim of counseling was to increase motivation and ability to change diet, physical activity, and smoking behaviors (patients chose which one[s] they wanted to focus on). Motivational interviewing and problem solving treatment were used to help patients find solutions to overcoming barriers and increase perceived control. In-person counseling sessions (weekly at first, then every 2–3 weeks) were followed by monthly telephone sessions.
	Usual care	Received written information about risk of developing diabetes and CVD and brochures containing health guidelines on physical activity, healthy diet, and smoking cessation. Patients with systolic blood pressure >160 mm HG and/or hypercholesterolemia (>8 mmol/L) were referred to their primary care provider for additional medication. Patients with glucose values >7.0 mmol/L were referred to primary care physician and then excluded from the trial.
Live Well Be Well, 2012 ⁸⁶	Healthy diet & physical activity counseling	Individually-tailored, phone-based lifestyle program designed for lower socioeconomic status, minority, and low-literacy adults and adapted from interventions with established efficacy. Offered in English and Spanish. Participants had an individual counselor and an introductory session (in-person), personal planning session (in-person), and followup calls and workshops. Program focused on self-monitoring, goal setting, and problem solving, and 2 key social cognitive theory concepts were taught to provide behavior change skills and increase self-efficacy. Six-month active phase was followed by 6-month maintenance phase. Counselor contact occurred mostly at the beginning and decreased over time. Physical activity focus promoted 30 minutes of moderate-intensity activity ≥5 days/week (150 minutes/week). Diet goals were to reduce calorie intake and total fat and increase fiber intake. "Eat Colors" and "Eat Breakfast" were used to enforce these goals. Education about health risks and benefits of healthy behaviors were delivered through written, phone, and in-person methods. Skills building was provided through training on goal setting, self-monitoring, problem solving, and relapse prevention. Motivational interviewing techniques were used during phone calls.
	Waitlist control	Waitlist control; started program after 12 months. During recruitment/enrollment, diabetes prevention materials were distributed.
Melbourne Diabetes Prevention Study (MDPS), 2012 ⁸⁵	Healthy diet & physical activity counseling	Based on the Life! program; comprised of structured group sessions every 2 weeks for the first 3 months, then the last session 8 months after the first. Sessions focused on problem solving and individually-tailored goals. Goals were based on the Finnish Diabetes Prevention Study: ≤30% calories from fat, ≤10% from saturated fats, ≥15 g/1000 kcal of fiber, ≥30 minutes/day moderate-intensity physical activity, and ≥5% weight reduction.
	Waitlist control	Usual care; offered the intervention after 12 months.

Appendix E. Intervention Descriptions of Included Studies by Intervention Focus and Intensity

Author, Year	Intervention	Description
PRO-FIT, 2012 ⁶⁸	Healthy diet & physical activity counseling	Developed according to the I-Change model (integrated model for exploring motivational and behavioral change), which targets 3 phases of the behavioral change process: 1) awareness, 2) motivation, and 3) action. The intervention is personalized health counseling and includes use of a Web site on CVD risk communication and how to change these risks; access to online PRO-FIT advice on positive behaviors such as food intake, smoking, and compliance to statin therapy, presented according to the participant's risk profile; and a lifestyle coach who delivers personal feedback and works with participants to make action plans. The goal of the intervention is to help participants adopt a healthier lifestyle with regard to physical activity, diet, smoking, and compliance to statin therapy and to lower the level of low-density lipoprotein cholesterol and other CVD risk factors, through use of online tools and a lifestyle coach.
	Usual care	Usual care (no intervention).
SPRING, 2012 ¹⁰⁰	Healthy diet & physical activity counseling	All patients receive counseling on CVD risk from practice nurses trained in motivational interviewing techniques. In the IG, this first meeting was based on self-monitoring results (pedometer, scale, and/or blood pressure device). SCORE risk assessments, present risk factors, and treatment goals were discussed. Participants had followup visits that proactively treated for all present risk factors. The order in which risk factors were treated depended on the preference and state of change of the participant, though quitting smoking was the first goal treated if applicable. Adapted motivational interviewing counseling was used. All treatment had to start within 3 months after initial meeting. All patients were offered self-monitoring tools (scales and pedometers) if applicable. For overweight participants: food diaries, home scales, pedometer, and tracking were used in addition to intensive counseling. For low physical activity participants: pedometers and diaries were used in addition to intensive counseling. For those with hypertension: home blood pressure monitoring was used in addition to intensive counseling.
	Minimal intervention	All patients receive 1 session of counseling on CVD risk from practice nurses trained in motivational interviewing techniques. SCORE risk assessments, present risk factors, and treatment goals were discussed at first visit. After the initial visit, followup visits for the CG followed the Dutch hypertension and hypercholesterolemia guidelines. Standard information leaflets were given to overweight participants, smokers, and low physical activity risk groups at first visit.
Anderson, 1992 ⁷⁰	Healthy diet counseling: AHA diet (IG 1)	Recommended nutritional targets derived from the AHA Phase II guidelines: 55% carbohydrate energy, 20% protein energy, 25% fat energy, ≤200 mg dietary cholesterol per day, and 15 g fiber. Individually-tailored, preplanned meal patterns with 3 servings fruits/vegetables; 4 starches/breads; 2 low-fat dairy; ≤198.5 g lean meat, poultry, or seafood; no egg yolks; fat servings based on energy content. Optional sweets and alcohol servings available. No additional recommendations on modification of other risk-relevant behaviors (e.g., smoking, exercise). Encouraged to attend small-group educational sessions with spouse/close friend; included demonstrations, problem solving, individual counseling (problems, questions about diet, goals). Home visits by dietitian; also available by telephone.
	Healthy diet counseling: high fiber (IG 2)	Same recommended nutritional targets as IG 1 except 50 g fiber (which was stressed during sessions); same preplanned meal patterns except at least 1 serving of beans and 1 of cereal. All other aspects identical to IG 1.
	Usual care	No details provided.
Moy, 2001 ⁷³	Healthy diet counseling	Individualized instructions to lower fat intake (based on ATP III guidelines), focusing on total fat consumption and daily monitoring (usually a goal of <40 g total fat); taught how to read food labels, use fat counter to monitor and record total daily fat intake; self-monitoring logs. Physicians asked to explicitly not manage dietary interventions as recommended based on results and feedback from baseline screening. At each visit, dietary fat screening instrument used to identify potential problems. Counseling individualized based on initial dietary habits, lifestyles, and progress.
	Usual care	Usual care from primary care physician. Physicians received patient-specific recommendations from results and feedback from the baseline screening for risk factor management on 3 occasions.
DEER, 1998 ⁷¹	Healthy diet counseling	NCEP Step 2 diet. Goals: <30% fat, <7% saturated fats, <200 mg cholesterol/day. Sessions included lessons on replacing dietary sources of saturated fat with complex carbohydrates, low-fat dairy foods, and other alternatives, including lean meats. Weight loss not emphasized.
	No advice	CG (no intervention). Asked to maintain usual diet and exercise.

Appendix E. Intervention Descriptions of Included Studies by Intervention Focus and Intensity

Author, Year	Intervention	Description
Delahanty, 2001 ⁷²	Healthy diet counseling	Cholesterol-lowering nutritional counseling and treatment according to NCEP-based protocol. Number of visits each participant received was based on assessment of each's eating habits, lifestyle, capabilities, and motivation for change, in addition to usual care from primary care physicians.
	Usual care	During the 6-month intervention, participants agreed to not use lipid-lowering drugs or to seek additional dietary counseling.
Hyman, 1998 ⁷⁶	Healthy diet counseling	Patients offered/encouraged to use multimodal counseling options (mailed dietary questionnaire, computer interactive calls, and classes) to make dietary changes to reduce cholesterol levels. Intervention focused on improving practical skills like reading labels, eating out, modifying recipes, and self-monitoring, while being practical for primary care.
	Usual care (waitlist control)	Usual care by primary care physician, hypercholesterolemic patients could be referred to registered dietitians. After trial, offered the series of classes (waitlist control).
Johnston, 1995 ⁷⁷	Healthy diet counseling (IG 1)	Small-group sessions on source and function of dietary cholesterol, risk associated with high cholesterol intake, debunking of dietary misconceptions, advice for eating out, and benefits of exercise. Partners invited to attend. All patients got basic information (see CG description).
	Healthy diet counseling (IG 2)	Nurse counseling: advised to make changes in food intake to reduce the amount of total and saturated fat; increase amount of dietary fiber and complex carbohydrates. Habitual diet estimated by questionnaire; total score and pattern of individual food sources used to suggest specific changes in food choices.
	Usual care	All patients given simple health questionnaire (basic information on diet and exercise) and verbal advice/pamphlet about diet modification, cooking methods, and physical exercise. No further counseling. Incidental queries from subjects were answered briefly on their return to clinic.
Tomson, 1994 ¹⁷⁴	Healthy diet counseling	Counseling intervention aimed at nonpharmacological management of high cholesterol; individualized counseling based on diet history and "step 1" or general lipid-lowering advice, low-fat diet, high-fiber diet; spouses were invited to the second session; group session included visiting a grocery store to learn how to identify low-fat and high-fiber foods.
	Usual care	Booklet with diet information was sent with a letter, and dietary recommendations based on the patient's weight was included. For those who were overweight: increase fiber and decrease fat intake to 30% of total daily calories. For those of healthy weight: switch to mono and polyunsaturated fats.
Ammerman, 2003 ⁷⁴	Healthy diet counseling	Special intervention with 3 components: 1) Food for Heart Program during tailored counseling sessions, 2) referral to local nutritionist if lipids remained elevated at 3-month followup, and 3) reinforcement during the second half of the intervention (phone call, 2 newsletters focusing on seasonal tips for food preparation and strategies to enhance dietary change). Food for Heart Program aimed to reduce consumption of foods high in saturated fat, increase fruit and vegetable intake and complex carbohydrates; individually tailored with goal sheets, pamphlets, and southern-style cookbooks. Participants were also instructed to see their physician if total cholesterol remained high.
	Usual care	Nurses instructed to provide counseling for high cholesterol as usual; participants instructed to see their physician if total cholesterol remained high.
Southeast Cholesterol Project, 1997 ⁸¹	Healthy diet counseling	Clinician-directed dietary counseling, including a Dietary Risk Assessment, which assesses sources of fat and cholesterol and enabled individually-tailored counseling via the Food for Heart Program; easy-to-read, culturally-tailored patient education materials; quarterly reinforcement mailing containing recipes and health tips. If low-density lipoprotein levels remained elevated after 4 months, then participants were referred to a dietician or health educator for up to 3 counseling sessions. At 7-months followup, primary care physicians received mailed reminders (based on NCEP guidelines for initiating drug therapy) to consider lipid drug treatment if the patient's low-density lipoprotein levels remained elevated.
	Usual care	No details provided.
Beckmann, 1995 ¹¹¹	Healthy diet counseling	Instructed to lower sodium intake (e.g., not adding salt at table or while cooking, avoiding sodium-rich foods, processed food; bake own bread; use oil, salt-free margarine; and increase fruits/vegetables); provided with a free 2-week supply of unsalted foods with aim to reduce average daily sodium intake to 30 mmol/day. After, aim of achieving average daily sodium intake of 100 mmol/day; those with elevated BMI or total cholesterol were advised to reduce body weight and reduce saturated and increase intake of polyunsaturated dietary fat.
	Waitlist control	At 12 months, given dietary advice similar to IG.

Appendix E. Intervention Descriptions of Included Studies by Intervention Focus and Intensity

Author, Year	Intervention	Description
Stevens, 2003 ⁸²	Healthy diet counseling	Combined motivational interviewing, problem solving, and social cognitive theory strategies; strategies for overcoming barriers and skills deficits interfering with dietary change or maintenance; opportunities for increasing environmental support; select 1 of 2 goals (reduce dietary fat or increase fruit/vegetable and whole grains); provided feedback on baseline dietary intake. Dietary fat goals were assisted with a computer assessment (30 minutes) and discussion of goals/plans for change (25 minutes) using the Fat and Fiber Behavior Questionnaire, which helped provide tailored strategies. Fruit and vegetable goals focused on barriers, self-efficacy, eating patterns, and stage of change. The second session, 2–3 weeks later, reported progress on current goal and counseled on other goal. Participants made commitments and personally tailored strategies for change, received telephone support after second session.
	Attention control	Attention control on breast self-exams and a 9-minute American Cancer Society video; self-help pamphlets; and barriers-based, problem-solving counseling on interest and motivation for conducting regular breast self-exams. No dietary recommendations.
NFPMP, 2002 ⁹	Healthy diet counseling	Nutrition information and counseling according to stage of change; practical aspects included reducing saturated fat intake, increasing unsaturated fat intake, and reducing total energy and fat intake. If no progress, intervention stopped. Information package: individualized feedback based on baseline values, educational materials to support aforementioned goals (e.g., short food variation list, menus); if action phase then referral to dietician.
	Usual care	No details provided.
ODES, 1995 ⁸⁰	Healthy diet counseling	Individualized dietary counseling and education on high-/low-density lipoproteins and weight reduction by dietary change. Recommended against low caloric intake early in day and heavier at dinner; moderate salt restriction in persons with elevated blood pressure; energy restriction in overweight persons; recommended increase in fish, fruits and vegetables, and complex carbohydrates and reduction in sugar and saturated fat. Individualized dietary program of the 5–10 most important points made during counseling session. Target body weight/reduction agreed. Followup dietary advice at 3 and 9 months.
	Waitlist control	Waitlist control offered dietary advice and physical training after 1 year.
Bloemberg, 1991 ⁷⁵	Healthy diet counseling	Individualized dietary advice based on habitual food intake and the "Guidelines for a Healthy Diet" of the Netherlands Nutrition Council; used computer to generate dietary advice based on actual dietary pattern. Aim of dietary advice to reduce total cholesterol by 1 mmol/L. One week after examination, discussed dietary advice and tried to convince adherence. Telephone calls to inquire about possible problems about dietary advice. Mailers provided information on healthy diet.
	No advice	Did not receive any advice to improve diet during the study period.
Neil, 1995 ⁸	Healthy diet counseling: dietician (IG 1)	Standard diet history taken and given individual advice on dietary habits and weight. Advised to reduce percentage of total dietary energy from fat to ≤30%; consume ≤10% of energy from saturated, monounsaturated, and polyunsaturated fatty acids; 50%–60% energy derived from carbohydrates, protein 10%–20%; daily intake of <300 mg cholesterol; 35 g fiber. Further advice given during a 10-minute appointment.
	Healthy diet counseling: nurse (IG 2)	Advised to make changes in food intake to reduce the amount of total and saturated fat; increase amount of dietary fiber and complex carbohydrates. Habitual diet estimated by questionnaire; total score and pattern of individual food sources used to suggest specific changes in food choices
	Usual care	Pamphlet containing dietary guidance consistent with advice provided by dietitian. Additional written advice after 2 months.
Watanabe, 2003 ⁹⁷	Healthy diet counseling	New dietary education. Individualized counseling aimed to reduce total energy intake by modifying dietary intake and adopt habits to prevent diabetes. Program consisted of 1) individual dietary counseling based on questionnaire results, with booklet illustrating recommendations for meals corresponding to the recommended daily allowance for total energy intake at 1 month; and 2) mailed materials at 6 months. Education aimed to reduce late-night total energy intake; keep protein energy at 15%–20%, fat at 20%–25%, and carbohydrates at 55%–60% of total energy intake; optimize intake of whole grains, fruits and vegetables, low-fat milk, beans, fish, meat, eggs, and maintain alcohol intake at an appropriate level by Japanese Diabetes Society and American Diabetes Association recommendations. Mailer included encouragement to improve dietary intake, related information, self-administered checklist corresponding to recommended daily allowances, and information on necessity of blood glucose control.
	Usual care	General oral and written information about results of health examination and questionnaire without detailed explanation; received conventional group counseling with a leaflet with general information for prevention of lifestyle-related disease.

Appendix E. Intervention Descriptions of Included Studies by Intervention Focus and Intensity

Author, Year	Intervention	Description
LIFE, 2010 ¹³⁰	Physical activity counseling	Home-based lifestyle intervention aimed to stimulate integrated physical activity into immediate environment during daily routines. Prior to randomization, all IG participants attended a group session on healthy aging and benefits of physical activity. Following randomization, IG 1 attended group sessions throughout intervention period. Sessions shared general information about endurance, strength, flexibility, and postural/balance training and to ensure correct performance of exercises. Brochure and pedometer distributed (with training on proper use and heart rate monitoring). An individual session with exercise instructor set up program specific to individual needs, preferences, and experiences. Participants given booklet with exercises targeting strength (using elastic tubes), flexibility, and balance, and asked to choose preferred exercises. Suggested endurance trainings included jogging, cycling, swimming, or other cardiovascular exercises; participants encouraged to exercise at intensity that increased heart rate but still able to talk with their partner. Individual session with exercise psychologist focused on how to integrate exercises into daily life, how to persist, and how to anticipate barriers. Participants asked to keep an activity log and referred to these during "booster" phone calls to discuss program adherence.
	Usual care	Prior to randomization of IG groups, CG volunteers attended a group session on different components of healthy aging (similar to the introductory session offered to IG volunteers, except it excluded the physical activity benefits component). CG volunteers were participating in a "checkup of fitness/health status" program, which involved getting measurements (3 times: pre-, mid-, post-) with no feedback or results until end of study period (after 11 months). Each participant was asked to report changes in lifestyle regarding physical activity, diet, or medication during the program.
Enhanced Fitness Trial, 2012 ⁹⁸	Physical activity counseling: reduced calls (IG 1)	Reliant on social cognitive theory, the strategy is to enhance self-efficacy for physical activity by integrating self-monitoring, goal setting, reinforcement, modeling, and cognitive function into counseling program. Five-element intervention, including: 1) In-person consultation with health counselor to assess functional status. 2) Primary care physician notified of participant enrollment and endorsed physical activity at next scheduled visit. At 3-month point, participant's physical activity performance was assessed and all those who met >75% of exercise goals (minutes per week) were assigned to IG 1 (reduced calls); those who failed to meet exercise goals (<75%) were allocated to IG 2 (continued care). 3) Health counselor contacted participant for followup counseling by phone, using standardized protocol to reinforce continued physical activity, identify strategies for overcoming barriers, and customize individually-feasible activities. 4) Automated phone calls with recorded messages from the primary care physician. 5) Quarterly tailored progress report, including a graph showing participant change over time and encouragement messages tailored based on participant performance. 6) Referral to local physical activity program (MOVE!).
	Physical activity counseling: continued care (IG 2)	Same as IG 1, with more phone call followup.
	Minimal intervention	Usual care received in primary care clinic plus referral to the MOVE! program (program on physical activity and nutrition that includes self-management programs, classroom sessions, and individualized counseling with goal setting). Participants sent lifestyle questionnaire and could decide whether to enroll in the program.
PAC, 2001 ¹²²	Physical activity counseling	All participants (IG and CG) given brief (2–4 minutes) physical activity counseling during routine visit with primary care provider. Using the 7A shared-care model for physical activity counseling, this brief intervention addressed the first 4 As: Address the subject of physical activity; Ask participants about their physical activity; Advise participants to increase physical activity while personalizing benefits; Agree on 1-month leisure-time physical activity goal. All participants then received a tailored physical activity prescription that included the agreed upon goal. The IG (intensive-counseling group) then received 6 patient-centered physical activity counseling sessions over 3 months from the physical activity counselor, focusing on the other 3 parts of the 7 A model: Assess, Assist, and Arrange. Counseling was highly individualized but always involved encouragement and support, helped participants set a goal and problem solve around potential barriers, and focused on psychological mediators of change.
	Minimal intervention	Brief (2–4 minutes) physical activity counseling intervention with primary care provider. Using the 7A shared-care model for physical activity counseling, this brief intervention addressed the first 4 As: Address the subject of physical activity; Ask participants about their physical activity; Advise participants to increase physical activity while personalizing benefits; Agree on 1-month leisure-time physical activity goal. All participants then received a tailored physical activity prescription that included the agreed upon goal. No further intervention afterward.

Appendix E. Intervention Descriptions of Included Studies by Intervention Focus and Intensity

Author, Year	Intervention	Description
PREPARE Trial, 2009 ⁹⁹	Physical activity counseling (IG 1)	Single-session group educational program designed to promote increased physical activity (primarily walking) by targeting perceptions and knowledge of impaired glucose tolerance, physical activity self-efficacy, barriers, and self-regulatory skills. Person-centered approach to participant education delivered in groups of 5–10, divided into 4 modules: 1) participant story (participants share their knowledge of impaired glucose tolerance and concerns about program); 2) professional story (overview of healthy glucose metabolism, prediabetes complications and risk factors, calculate risk scores); 3) diet (link between diet and metabolism); 4) physical activity (how physical activity improves glucose control; understand physical activity recommendations; discuss how to incorporate physical activity into daily life; form action plans and set goals; encourage use of physical activity diaries). Only method of goal setting differed between IG 1 and 2. Both groups (IG 1 and 2) had brief 1-on-1 followup counseling with trained educator at 3 and 6 month clinical measurement session. Goal setting: IG 1 (PREPARE group): set physical activity goals based on generic exercise recommendations (i.e., 30 minutes of moderate-intensity exercise on most days of the week). Encouraged to set proximal goals, such as increasing moderate-intensity activity by 5 minutes/day every 2 weeks. Use of action plans and activity logs recommended.
	Physical activity counseling (IG 2)	IG 2-PREPARE and pedometer: received pedometer and trained on its use. Set personalized goals of steps per day based on baseline ambulatory activity levels and step per day categories. Generally recommended to increase by 3,000 steps per day, unless baseline was at $\geq 9,000$ steps, then recommended to sustain. Set proximal goals with timeline. Encouraged to wear pedometer on daily basis and to monitor activity using a log.
	Usual care	Brief information sheet in the mail detailing the likely causes, consequences, symptoms, and timeline associated with impaired glucose tolerance, along with information about how physical activity can be used to treat/control the condition.
Kallings, 2009 ¹⁴¹	Physical activity counseling	Usual care (1 page of physical activity education) plus brief physician message plus individual patient-centered motivational counseling plus physical activity prescription including participant's goals (including specific type of physical activity, frequency, and intensity). Given pedometers and education materials; encouraged to maintain physical activity diary. Participants encouraged to gradually increase levels until they met the recommended ≥ 30 minutes of moderate-intensity physical activity on most (preferably all) days of the week, including aerobic and strength training and exercises for improved flexibility and balance. Encouraged to reduce sedentary time. Group support session to which patient was encouraged to bring family member or friend; letter with individualized advice from physician; brief phone call.
	Usual care	One page of general information about importance of physical activity for health. Baseline measurement results provided 1–2 months following assessment.
NERS, 2012 ¹⁰⁹	Physical activity counseling	IG participated in 16-week tailored exercise program supervised by a qualified exercise professional. IG provided with 1-on-1 initial consultation with exercise professional to complete lifestyle questionnaire, health check, motivational interviewing, and physical activity goal setting using patient-centered approach, and introduction to leisure centers (sport/community centers). IG given option to take part in 1-on-1 exercise instruction or attend group classes at discounted rate (£1 per session). Primary goal was to achieve 30 minutes of moderate physical activity on ≥ 5 days/week. Exercise professional followed up with IG at specified time points to review goals, provided additional motivational interviewing, and support to encourage attendance and prevent relapse.
	Waitlist control	Usual care and a leaflet highlighting the benefits of exercise, including a Web site address listing locations of local leisure facilities.
PACE, 2005 ¹³¹	Physical activity counseling	Participants met with general or nurse practitioner for 10-minute consultation to discuss medical condition(s), offer advice about becoming more physically active, and assess stage of change for physical activity. Provider counseled the patient using the PACE program, the goal of which is to "promote long-term participation in regular physical activity by altering social and psychological factors known to influence physical activity, such as social support, increased self-efficacy, reduced perceived barriers, and increased awareness of the benefits of physical activity." Providers received 1-hour individualized training on PACE approach to increase knowledge and coach on use of PACE materials. PACE physical activity counselors (separate from general/nurse practitioner) provided 2 "booster" phone call consultations (2 and 8 weeks after initial visit), to offer support and resolve possible problems or questions. After initial visit, 1 followup visit with provider (4 weeks), where they focused on stage-specific protocols and checked on participant progress. At 4-week visit, offered new counseling protocol for those who had either progressed or regressed through stages of change.
	Usual care	General practitioners discussed patient's current level of physical activity and, as appropriate, encouraged patient to become more active. Standard text on physical activity promotion was provided.

Appendix E. Intervention Descriptions of Included Studies by Intervention Focus and Intensity

Author, Year	Intervention	Description
Green Prescription Programme, 2003 ¹²³	Physical activity counseling	Primary care clinicians (medical doctors and nurses) received 4 hours of training on how to use motivational interviewing techniques to advise on physical activity and the "green prescription." Following screening, patients given a prompt card with their stage of change, which they gave to their primary care provider (doctor [85%] or nurse [15%]) during their upcoming consultation. The prompt card cues clinician to discuss increasing physical activity and to set appropriate goals with the participant (usually home-based physical activity or walking). Goals are written on a green prescription, given to participant, and faxed to local sports foundation, along with details such as age, weight, health conditions. Exercise specialists from the foundation then call the patient ≥3 times in the next 3 months to encourage and support physical activity through motivational interviewing. Participants receive quarterly newsletters from the sports foundation about physical activity initiatives in the community; interested participants also receive other motivational materials, such as information on specific exercise programs. Clinician staff from general practice are encouraged to provide feedback to the patient during subsequent visits.
	Waitlist control	Usual care.
Moreau 2001 ¹⁰⁴	Physical activity counseling	Walking program to reduce blood pressure. IG were given pedometers at baseline and instructed how to wear (belt or waistband, morning to bedtime). After 1–2 week baseline measurement, IG provided a target goal to gradually increase the distance they walked (from 1.4 km over baseline to a 3-km increase in walking by week 3, as recommended by the American College of Sports Medicine and the Centers for Disease Control and Prevention). Walking steps recorded on daily log sheets with other physical activities and turned in every 2 weeks. IG presented to laboratory for measurements at 3 time points: baseline, 12 weeks, and 24 weeks.
	No advice	CG asked not to change daily activity and wore pedometer for 1 week each month to document their walking.

Abbreviations: AHA = American Heart Association; ATP = Adult Treatment Panel; BMI = body mass index; CG = control group; CME = continued medical education; CVD = cardiovascular disease; IG = intervention group; IT = information technology; JNC = Joint National Committee; NCEP = National Cholesterol Education Program; NHLBI = National Heart, Lung, and Blood Institute.
