

Doravirine

Updated: April 12, 2019.

OVERVIEW

Introduction

Doravirine is a nonnucleoside reverse transcriptase inhibitor used in combination with other antiretroviral agents in the therapy of human immunodeficiency virus (HIV) infection. Doravirine is associated with a low rate of transient serum aminotransferase elevations during therapy but has not been implicated in cases of clinically apparent acute liver injury.

Background

Doravirine (dor" a vir' een) is an antiretroviral agent that acts by noncompetitive binding to, and inhibition of, the HIV reverse transcriptase. Doravirine is a nonnucleoside reverse transcriptase inhibitor similar in action to nevirapine, efavirenz, delavirdine, etravirine and rilpivirine. In several randomized controlled trials, doravirine was found to have similar efficacy to efavirenz when combined with at least two nucleoside analogues (typically tenofovir and emtricitabine or lamivudine). Doravirine was the sixth nonnucleoside reverse transcriptase inhibitor approved by the FDA [2018], and current indications are for the treatment of HIV infection in combination with other HIV medications. Doravirine is available under the brand name Pifeltro in tablets of 100 mg. The recommended dose is 100 mg orally once daily. Doravirine is also available in a fixed dose (100 mg), oral once-a-day combination with lamivudine (300 mg) and tenofovir disoproxil fumarate (300 mg) under the brand name Delstrigo [2018]. Antiviral resistance can occur and resistance patterns are similar to, but somewhat less frequent than, those due to other nonnucleoside reverse transcriptase inhibitors. Common side effects include fatigue, dizziness, headache, diarrhea, nausea, disturbed sleep, abnormal dreams and skin rashes. Uncommon, but potentially severe adverse events include hypersensitivity reactions and immune reconstitution syndrome.

Hepatotoxicity

Serum aminotransferase elevations were reported in 13% of patients on doravirine therapy, but elevations above 5 times the upper limit of normal were uncommon, occurring in 1% or less of patients. The rate of serum aminotransferase elevations during doravirine therapy was higher in patients who were coinfecting with hepatitis B or C, but the abnormalities were rarely severe. Doravirine has been in clinical use for a short time only, but unlike many other nonnucleoside reverse transcriptase inhibitors, doravirine has yet to be linked to reported instances of clinically apparent liver injury.

Likelihood score: E* (suspected but unproven cause of clinically apparent liver injury).

Mechanism of Injury

Clinically apparent hepatotoxicity from doravirine has not been reported, but liver injury from other nonnucleoside reverse transcriptase inhibitors appears to be due to hypersensitivity. Doravirine is extensively metabolized in the liver via the cytochrome P450 system (predominantly CYP 3A4) and is susceptible to drug-drug interactions with modulators of CYP 3A4. Its use with strong CYP 3A4 inducers should be avoided because of potential decreases in doravirine plasma concentrations.

Outcome and Management

Doravirine therapy has been linked to mild and self-limited serum aminotransferase elevations which rarely require dose modification or discontinuation. Doravirine has not been linked to cases of acute hepatitis, acute liver failure, chronic hepatitis or vanishing bile duct syndrome. There is no information on cross sensitivity to hepatic injury between doravirine and other nonnucleoside reverse transcriptase inhibitors, although there may be cross reactivity in occurrence of rash.

CHEMICAL FORMULA AND STRUCTURE

DRUG	CAS REGISTRY NUMBER	MOLECULAR FORMULA	STRUCTURE
Doravirine	1338225-97-0	C ₁₇ H ₁₁ ClF ₃ N ₅ O ₃	 <p>The chemical structure of Doravirine is shown. It features a central pyridine ring with a trifluoromethyl group (-CF₃) at the 2-position, a cyano group (-C≡N) at the 4-position, and a chlorine atom at the 5-position. An oxygen atom at the 3-position of the pyridine ring is linked to a 4-methyl-1H-imidazole-2-ylmethyl group. The imidazole ring has a methyl group (-CH₃) at the 4-position and a carbonyl group (=O) at the 2-position.</p>
