

Venetoclax

Updated: April 4, 2017.

OVERVIEW

Introduction

Venetoclax is an oral selective BCL-2 inhibitor and antineoplastic agent used in the therapy of refractory chronic lymphocytic leukemia (CLL). Venetoclax is associated with a low rate of transient serum enzyme elevations during therapy, but has not been implicated in cases of clinically apparent acute liver injury with jaundice. Venetoclax has potent immunosuppressive activity and may be capable of causing reactivation of hepatitis B.

Background

Venetoclax (ven et' oh klax) is a small molecule inhibitor of BCL-2, an intracellular protein that inhibits apoptosis. BCL2 is overexpressed in cancer cells, particularly in chronic lymphocyte leukemia (CLL). Overexpression of BCL2 increases cancer cell survival and increases resistance to chemotherapy. Venetoclax binds directly to BCL2 and blocks its antiapoptotic activity, leading to programmed cell death in the malignant B cells. Venetoclax was found to have activity against refractory and relapsed CLL and was approved for use as an antineoplastic agent in the United States in 2016. Current indications are limited to therapy of previously treated patients with CLL and an accompanying 17p chromosomal deletion (which is associated with a poor prognosis and resistance to standard chemotherapy). Venetoclax is available as tablets of 10, 50 and 100 mg under the brand name Venclexta. The typical initial adult dose for CLL 20 mg once daily for one week with gradual dose escalation (“ramp-up”) to as much as 400 mg daily. Side effects are common and include bone marrow suppression, neutropenia, infections, fever, diarrhea, nausea and vomiting, anorexia, abdominal discomfort and fatigue. Severe side effects include pneumonia, neutropenic fever and sepsis, autoimmune hemolytic anemia, embryo-fetal toxicity and tumor lysis syndrome (for which prophylactic measures are recommended during the ramp-up period).

Hepatotoxicity

In clinical trials in 240 patients with CLL, serum aminotransferase elevations occurred in 20% of subjects treated with venetoclax, but the elevations were generally transient, mild and not associated with jaundice or symptoms. In the preregistration trials, no cases of clinically apparent liver injury attributed to venetoclax were reported and few patients required drug discontinuation for liver test abnormalities. Since approval, venetoclax has had limited clinical use, but has not been implicated in cases of clinically apparent liver injury. Venetoclax decreases total white blood cell counts and can cause lymphopenia in addition to neutropenia. As a consequence, venetoclax may be capable of inducing immune reactions including reactivation of hepatitis B. However, instances of reactivation have not been reported, but neither has detailed information on the effects of venetoclax on hepatitis B virus levels in patients with preexisting hepatitis B or evidence of previous infection.

Likelihood score: E (unlikely cause of clinically apparent liver injury).

Mechanism of Injury

Venetoclax is unlikely to have direct hepatotoxic effects as dose escalation studies showed no dose related effect on liver test results. On the other hand, the immunosuppressive effects of venetoclax may cause liver related changes that could lead to viral or autoimmune reactions. Venetoclax is metabolized in the liver, largely via CYP 3A4 and is susceptible to drug-drug interactions with inhibitors or inducers of CYP 3A or in inhibitors or substrates of P-glycoprotein.

Outcome and Management

Patients receiving venetoclax require careful monitoring largely for hematologic abnormalities and blood chemistry changes of tumor lysis syndrome. If serum aminotransferase levels rise to 5 times the upper limit of normal (ULN), therapy should be interrupted until levels fall to baseline or less than 1.5 times ULN.

CHEMICAL FORMULA AND STRUCTURE

DRUG	CAS REGISTRY NO	MOLECULAR FORMULA	STRUCTURE
Venetoclax	1257044-40-8	C ₄₅ H ₅₀ Cl- N ₇ O ₇ -S	 <p>The chemical structure of Venetoclax is a complex organic molecule. It features a central benzene ring substituted with a nitro group (-NO₂) at the 1-position, a piperidine ring at the 3-position, and a sulfonamide group (-NH-SO₂-) at the 4-position. The sulfonamide group is further substituted with a 1H-indole ring at the 5-position. The benzene ring is also connected via a methylene bridge to a piperazine ring, which is in turn connected to a cyclohexane ring. The cyclohexane ring has two methyl groups (-CH₃) at the 1-position and a 4-chlorophenyl group (-C₆H₄-Cl) at the 2-position.</p>
